The last of the substances necessary to be noticed in this section of the second division of diaphoretics is *water*. The greater part of the fluid perspired by the skin is water; and if the surface be kept warm, so as to check the action of the kidneys, the proportion is generally in the ratio of the quantity of fluid taken into the stomach. But besides this cause of the diaphoretic influence of water, it is also well known that the sudden impression of a draught of cold water upon the nerves of the stomach acts most forcibly in promoting diaphoresis. A person who awakes in the night with the tongue feverish and parched, a quick pulse, and a dry, hot skin, finds immediate relief from swallowing a large draught of cold water: the cutaneous capillaries immediately consent with the stomach, and copious perspiration often ensues. By imitating this practice in fevers a similar result is occasionally obtained. When water is to be employed as a diaphoretic, much depends on the management of the patient during its administration. If the surface be kept warm, and the body surrounded with bad conductors of caloric, a moderate quantity of water will produce the effect required. Under these circumstances, cold water is to be preferred to warm; but it must be kept in remembrance that in delicate constitutions, even in fever when the excitement is high, a sudden reduction of temperature is hazardous,

and, therefore, tepid drinks are necessary; and small quantities of aromatics may be added to the aqueous fluid to moderate the nausea which tepid water always produces.

Besides being diaphoretic itself, water is the general auxiliary of all other diaphoretics; nor can the influence of the best of them be maintained without ample dilution. In this case the fluid employed should always be tepid, at least of a temperature not under 65° Fahrenheit. The same rule, indeed, is necessary for the administration of diluents as for the external employment of water; when the temperature of the body is under 96°, cold drink should not be ordered. Nature points out the best indications for using water, both as to its administration at first and its continued employment, by the sensation of thirst which accompanies every state of febrile action: when this is present, we cannot err in prescribing water, the temperature being determined by that of the body and the state of the skin.

Among those substances which enter the circulation and operate as diaphoretics by their direct influence on the skin, the first which we have to notice is *sulphur*. When this substance is taken into the stomach, it passes off through the cutaneous exhalants united with hydrogen; a fact demonstrated by silver, worn in the pockets of those taking it, assuming the same dark hue as if it had been exposed to a stream of sulphuretted hydrogen gas; and as it thus passes off, it excites diaphoresis. As a diaphoretic, sulphur is employed in cases of chronic rheumatism and some other skin diseases; and in combination with oil, the oleum sulphuratum of the London Pharmacopœia, in chronic catarrh: but this is an acrid, nauseous preparation, and consequently seldom administered. In combination with potassium, sulphur forms a solid preparation, hepar sulphuris, which by solution in water is converted into a hydro-sulphuret of potassa. Both of these preparations have been employed as diaphoretics in chronic affections of the chest, and in several cutaneous diseases.

The action of the salts of *mercury* upon the capillary system has been long known; and in having the cuticular discharge promoted by them, it is probable that the skin only shares, as a secreting organ, in the general influence which they exert on the glandular system; but although their influence on the cutaneous function is demonstrated by daily experience, yet they are only employed as auxiliaries in promoting diaphoresis. Calomel, the protochloride of mercury, is the preparation usually selected for obtaining the effect of mercury on the cuticular exhalants; and it is generally conjoined with tartar emetic or James's powder, ipecacuanha, guaiacum, or opium; to which it imparts additional sudorific power. In these combinations, calomel is given with advantage in all inflammatory diseases; and, in the form of Plummer's pill, in cutaneous eruptions and in chronic rheumatism. In this pill the antimonial is the antimonii sulphuretum præcipitatum of the London College, a preparation possessing more certain sudorific properties than the pulvis antimonialis: whether an influence can be ascribed to the guaiacum, considering its small proportion to the more active ingredients in this

pill, seems doubtful. As a diaphoretic, the dose of calomel should not exceed one grain, frequently repeated.

c. Whether sweating or mere diaphoresis be produced, the cause of both, as far as they are the result of the substances to which we have already referred, is the augmented action of the whole vascular system; but diaphoresis may be procured by the excitement merely of the cutaneous capillaries. The natural insensible perspiration is, indeed, apparently the effect solely of the cuticular system of vessels; and although means exist by which this may be carried to sweating, yet still the cause is confined solely to the cuticular vessels. *Friction* operates in this way, acting on the surface, in a manner equivalent to muscular exertion on the whole habit, in augmenting diaphoresis. The *tepid bath* produces its effects on the same principle, although both the degree and the nature of the stimulus be different. When the tepid bath is employed, it is necessary to continue the application for a considerable time to produce the desired effect. The first result of its application is emollient, the second diaphoretic.

In remarking on the practical employment of diaphoretics, we should say that they must be selected according to the nature of the disease, and the object to be accomplished. Those that operate by augmenting the force of the general circulation are well adapted for relieving internal congestions; those which produce nausea and unload the oppressed capillaries, are adapted for diminishing febrile action, and reducing the morbid temperature of the body.

With respect to the diseases in which diaphoretics are beneficial, we must refer to the various articles which are devoted to their consideration.

[It may, however, be doubted whether we have any internal remedies that are capable of acting as direct diaphoretics,—that is, by virtue of specific properties which they possess over the glandular or diapnogenous apparatus of the skin. In every case in which the skin is hot and dry, and the indication appears to be to establish diaphoresis, the cause of this condition of the cutaneous exhalants must be inquired into, and if possible removed. Hence it is, that the well-instructed practitioner employs *indirect* diaphoretics rather than such as are esteemed *direct*. Thus, diminished sensible exhalation takes place from the skin during the existence of fever or inflammation, but the physician does not have recourse to any reputed diaphoretic, which acts by exciting the sanguiferous system. He adapts his antiphlogistic remedies so as to reduce the already too much excited condition of the blood-vessels, to the healthy standard; and he finds, when he has removed the internal inflammation, the heat and dryness of the skin subside, and diaphoresis satisfactorily established. Under similar circumstances, a full dose of opium is attended with a similar result. Opium in a full dose is a sedative; and hence morphia, in large doses, is often so powerfully diaphoretic. Nauseants are most effective diaphoretics in diseases of excitement; and they are powerful sedatives. On the whole, even in febrile and inflammatory affections, the use of the ordinary internal diaphoretics is uncertain, and generally of no avail; and many of them are de-

cidedly injurious by their excitant properties; yet, in many such cases, advantage may be derived from the equalizing influence of the warm-bath; and in minor inflammations, especially of the gastro-pulmonary mucous membrane,—as catarrh,—warm diluents, aided by the warmth and quietude of bed, produce an equalizing effect, which is often most salutary.

In almost all cases in which the employment of diaphoretics appears to be indicated, the class of sedatives, (*q. v.*) or refrigerants, (*q. v.*) or both, will be found infinitely more advantageous. (*General Therapeutics*, &c., i. 312.])

A. T. THOMSON.

**DIARRHŒA**, (*Διάρροια*, from *διάρρῶ*, *perfluo*, primarily from *διὰ*, *per*, and *ῥέω*, *fluo*); looseness, flux, lax. This is a very common and well-known disease, characterised by frequent and imperative calls to go to stool, the evacuations being more liquid than the usual healthy discharges from the bowels. Pain or griping is occasionally an attendant, but not necessarily so. This disorder is frequently a matter of trifling importance; at other times it is productive of serious consequences.

**Causes.**—Diarrhœa may originate in very various causes. One of the most common is the direct application of stimulants to the interior of the digestive tube. Errors in diet, either in quantity or quality, will often act in this way. When a great mixture of different kinds of food and drink is taken at the same meal, a sudden attack of diarrhœa is no uncommon occurrence, and need not be matter of surprise. In some constitutions a draught of cold water, beer, milk, &c. immediately affects the bowels, especially if the individual is heated at the time; and ices are often productive of the same effect. Unwholesome articles of diet operate in a similar manner on many individuals. Of this kind are, animal food approaching to a putrid state, raw vegetables, cucumbers, melons, mushrooms, certain salads, &c.\* Diarrhœa is also a very common occurrence in infants when the nurse's milk disagrees, or when other food is given too stimulant for their digestive powers, or in too great quantity.

Diarrhœa occurs as a sympathetic disorder in many diseases, as in the dentition of children; and there are many affections of a more general kind where it is a frequent attendant. Measles, scarlatina, and other exanthemata, afford examples of this. In such cases there is little doubt that an excited or hyperemic state of the mucous membrane takes place: some have even supposed that an eruption analogous to that on the surface may be present. In gastric and enteric fevers, also, diarrhœa is a frequent symptom. It is often the initiatory state in cholera and dysentery; and in some diseases, as fevers, it occasionally shows itself as a critical discharge. The diarrhœa which attends the latter stages of phthisis, and other

forms of hectic and atrophic affections, is universally known.

Many causes give rise to diarrhœa in a less direct manner, such as exposure to cold, cold and wet feet, an atmosphere simply cold and damp, or impregnated with putrid exhalations, &c. With some persons exposure to warm and damp air is productive of the same consequences; and alternations of temperature are often equally effective, as in the case of a hot day being succeeded by a chilly evening. Suppressed evacuations, as interrupted sweat, checked menstruation, the disappearance of abscesses, retrocession of the eruption of smallpox, measles, or scarlatina, are occasionally succeeded by diarrhœa. Many persons of a nervous temperament are subject to similar attacks on the least agitation of mind, anxiety, or surprise; and when such mental states are present, the slightest errors of diet will be followed by liquid discharges from the bowels, although the same persons are exempt from any such attacks when no such disturbing causes are in operation, even when they indulge in a great variety of food. Morbid secretions from the liver and other glands that open into the intestinal canal, as well as irritating secretions from the mucous membrane itself, are also causes of diarrhœa. So likewise are worms generated there; but less frequently than might be expected.

Gout in many instances appears to maintain a tendency to loose discharges from the bowels, and to expend itself by this outlet. We have known several cases of persons who were accustomed to have three or four loose motions daily while in health; and when the least interruption to this ordinary habit took place, a fit of regular gout came on, the diarrhœa re-appearing when the gouty attack had subsided. One gentleman had his first attack of gout on giving a check to a loose state of the bowels which he considered troublesome; and for many years afterwards diarrhœa and gout constantly alternated. This is the *diarrhœa arthritica* of Sauvages, and is noticed by many practical writers, as Sydenham, Baglivi, Musgrave, &c. Many persons are liable to diarrhœa on visiting certain cities, as London, Paris, Cork, Limerick, Galway, &c. The waters of such places are commonly accused as producing the complaint, but there are probably other causes. Diarrhœa often prevails epidemically without our being able to trace the precise cause; but in such cases it is commonly accompanied by catarrhal affections of other mucous membranes.

**Symptoms and different forms of Diarrhœa.**—An attack of diarrhœa is, in most instances, from whatever cause it may proceed, preceded by feelings of indigestion, nausea, flatulence, &c. It is usually attended by more or less pain or uneasiness in different parts of the abdomen, more especially before the bowels are called upon to act. In the more severe forms, the abdomen is often swelled, hot, and painful to the touch, and the discharges are announced by searching pains of various degrees, sometimes slight, sometimes very severe, and attended occasionally by fainting, and frequently by nausea, or even vomiting. The pain seems to follow the transit of the alimentary mass, and to be connected with the peristaltic contractions of the muscular coat of the intestines.

\* We have the personal testimony of no less a man than Cicero, that the substances last mentioned are productive of this complaint.—*Dum volunt isti lauti terra nata, quæ lege excepta sunt, in honorem adducere, fungos, helvellas, herbas omnes ita conduunt, ut nihil possit esse suavius. In eas quum incidissem in cæna augurali apud Lentulum, tanta me διάρροια arripuit, ut hodie primum videri consistere. Itaque ego, qui me ostreis et murensis facile abstinebam, a beta etiam et a malva deceptus sum.*—*Epist. Fam. lib. vii. 127.*

The discharges take place without effort, and in some instances are involuntary. The patient feels weaker after each evacuation, yet experiences some relief from the pain, tension, and flatulent working in the bowels.

The number of stools is very uncertain; they may amount to ten, fifteen, twenty, or even twice that number, in the twenty-four hours. In the commencement of the attack they are abundant in quantity; afterwards they become more scanty, and, whatever may have been their original condition, consist chiefly of a serous fluid mixed with fibrous threads. The discharges are more fetid in proportion to the quantity of proper excrementitious matter contained in them. Paleness and wasting of the body accompany the severer attacks; likewise a sense of chilliness, dry skin, a loaded tongue, and a diminution of the urinary secretion. The patient becomes often so enfeebled as to be forced to keep his room or even his bed.

The nature of the evacuations in diarrhœa has of course attracted the attention of physicians in a very particular manner, and in most cases they have been considered as constituting the very essence of the disease. The discharges vary extremely in colour, consistence, and other physical characters; and although this variety is often observable in individual cases, either at one and the same instant, or at different periods of the attack, still, generally speaking, different cases commonly preserve throughout their course one predominant character of the evacuations. On this fact has been founded the most common classification of diarrhœa which we possess, and which, variously modified, has obtained from the earliest times up to the present period. This classification is, no doubt, as we have just observed, founded in nature; still it must be strongly impressed on the mind of the student and young practitioner, that the nature of the stools alone cannot be admitted as affording a true indication of the pathological condition of the parts which constitute the seat of the disease, and much less as a guide in practice. Constant attention to their character, however, can never be dispensed with on the part of the practitioner.

For a full account of all the appearances of the discharges which have been considered as characterising different species or varieties of diarrhœa, we must refer to nosologists and systematic writers. We can only notice a few of the most remarkable.

*Feculent diarrhœa.*—The evacuations in this variety are of the ordinary fecal character, but more liquid and more frequent than natural. This may be said to be present in the commencement of all the other forms, inasmuch as the fecal contents of the bowels must be evacuated either before the morbid secretions take place, or in conjunction with them. What, however, has been usually termed feculent diarrhœa, is that in which the evacuations retain this character through the greater part of their course. This is the *D. stercorea* of Sauvages, the *D. crapulosa* of Cullen, and the *D. fusa* of Good. It is apt to occur to those who have large appetites, and who have overloaded the stomach with a variety of food. It often comes on without warning and without pain. It is sometimes attended with dyspeptic symp-

toms, but sometimes not. It generally ceases of its own accord; and though it leaves the patient somewhat debilitated, the healthy functions of the bowels are soon restored, provided the patient or his attendants are not too anxious prematurely to arrest the discharges, or again to overload the stomach with improper food.

*Bilious diarrhœa.*—This is not a very uncommon form of bowel disorder, yet we believe it is often said to be present when the affection is merely that last described. In the proper bilious diarrhœa, the stools, at first fecal, are loaded with a morbid proportion of bile, and are, in consequence, of a bright yellow or greenish colour. It is supposed to arise from an excited condition of the liver producing a superabundant secretion of bile, or bile of a morbid character, which acts on the mucous membrane of the bowels as a stimulant. This state of the liver is frequently produced, we believe, by a primary affection of the duodenum, of an inflammatory kind, which either simply excites the gland to increased action, by what has been termed continuous sympathy, or produces in it a like condition with itself. In either case the result is an augmented flow, and probably a depraved state of the bile. This species of diarrhœa is often met with in those who live intemperately, or whose hepatic organs have suffered in warm climates. Intense moral emotions, such as a violent fit of anger in sanguine temperaments, or grief and disappointment in melancholics, have been observed to give rise suddenly to it. The connection between the manifestation of the passions of the mind and the secretion of bile, so familiar to our classical readers in the writings of the ancient physicians as well as poets, is founded in accurate observation, and no doubt originated in the supervention of the form of diarrhœa now under consideration, to strong mental emotions. All our nosologists agree in terming this variety *D. biliosa*.

*Mucous diarrhœa.*—In the true mucous diarrhœa, the stools contain little or no proper fecal matter, but consist chiefly of mucous or watery fluids, the former being predominant. The stools sometimes consist entirely of mucus, which is passed either in large continuous masses, or in separate flakes, intermixed with more liquid matters; it is often found, particularly in the commencement of an acute attack, or rather, after this has lasted a few days, quite transparent, and of the consistence of jelly; at other times it lies at the bottom of the pan like semi-transparent mucilage. The stools are of very various colours, depending chiefly on the degree of admixture with bile, but the characteristic features of the variety are to be sought for rather in the consistence and tenacity than in the colour. This form of diarrhœa is usually acute, and often reigns epidemically in conjunction with mucous fevers and catarrhal affections of the other mucous membranes, with some of which it occasionally alternates. It is often unaccompanied with fever, even when of considerable severity; sometimes, however, there is a very marked febrile state. It sometimes assumes a more chronic or sluggish course in old delicate valetudinarians, who suffer from dyspeptic, hypochondriac, and other chronic ailments. In such cases, both the stomach and

bowels are often loaded with depraved mucus secreted in great quantity, and which appears to be the cause of the diarrhœa. In cases of this kind the mucous membrane is sometimes found thickened and congested, and the mucous follicles are erected and patulous; and unless a suitable treatment is adopted, the disease degenerates into a permanently chronic state, probably with atrophy or dropsy. This is the *D. mucosa* of Cullen and Good, the *Cœliaca mucosa* of Sauvages.

*Serous diarrhœa.*—In this form the discharges are quite serous or watery, and hence it has been termed *diarrhœa aquosa* by many authors. The stools may be coloured variously, or they may be nearly colourless; they may be almost limpid or intermixed with minute flakes or shreds. Sometimes they are intermixed with mucus, but their characteristic feature is their being copious and watery. In some cases the quantity of fluid passed is very great, and speedily induces extreme debility. It is not always easy to distinguish this variety from cholera.

Serous diarrhœa may be produced under the same circumstances as the mucous variety, and then it must be considered as an acute disease, and as being, in many cases at least, dependent on an excited or inflamed state of the mucous membrane of the bowels. At other times it would appear as if the serous discharge originated in an opposite condition of this part, the exhalents pouring out their contents rather from loss of tone, and passively, than by an active organic process. It sometimes succeeds profuse perspirations suddenly repressed, or the imprudent use of acids and cold drinks when the body has been heated. It is sometimes the mode in which nature relieves herself from other diseases, as in dropsy, which has been known entirely to disappear on the supervention of a profuse diarrhœa of this kind. In very severe cases the discharges are so copious, and the emaciation and exhaustion so great, that it would appear as if almost the entire contents of the exhalent system were thrown upon the intestines. A marked form of this species is the diarrhœa of infants, termed *watery gripes*, in which the stools are often purely serous. This is the *D. serosa* of Sauvages and Good: it is included under the last variety (*mucosa*) by Dr. Cullen.

There is a variety of diarrhœa termed *tubularis* by Dr. Good, and which may be more properly named flaky or membranaceous. It is more entitled to notice as throwing some light on the pathology of the disease than as a distinct species of diarrhœa. In this variety there is a discharge of coagulable lymph, generally in the form of shreds or bands of more or less extent, and sometimes retaining the tubular shape of the bowel, whence Dr. Good derived his specific epithet. Such discharges are certainly met with in relaxed states of the bowels, but they are still more generally, perhaps, observed in cases where constipation is the habitual state. The fact is, that the peculiar inflammation of the mucous membrane, which gives rise to this morbid secretion, may produce either constipation or diarrhœa; and it is probable that when the former state exists, the seat of the disease is in the small intestines, and when the latter, in the large intestines. We have

frequently observed these fibrinous discharges in cases of temporary diarrhœa supervening to a long-continued state of constipation, whether excited by improper diet, purgative medicines, or occurring without any obvious cause. Such cases are, in fact, examples of chronic enteritis, and not of diarrhœa.

The *chylous* or *milky* diarrhœa of authors, and that termed *gypseous* or *chalky* by Dr. Good, are both denominated from false notions of their nature. We believe that the whiteness in the one case is no more owing to the presence of chyle, than in the other it is produced by lime, as Dr. Good supposed. The chief cause of the white colour in both these varieties is, no doubt, the absence of bile of the natural character or quantity; but as this may occur in very different states, and when the discharges are in other respects very different, there is no sufficient reason for establishing any distinct form of disease on these grounds. It is proper to observe, however, that in chronic cases when the stools are of this colour, and more particularly if they resemble an admixture of chalk and water, as described by Dr. Baillie (Med. Trans. vol. v.), they for the most part indicate a disease of a serious, often of a dangerous character.

The variety termed *lientery*, in which undigested aliment appears in the stools, has no claim to be considered as a distinct form of diarrhœa, as the circumstance supposed to characterise it may occur in every species of the complaint.

**Nature of the Disease.**—The foregoing account of the principal phenomena and more marked varieties of diarrhœa has necessarily anticipated much that might be said under this head. We shall therefore content ourselves with a few additional observations. "It is with difficulty," says Dr. Cullen, "that I have arranged this genus, as it is not very consistent with our plan to let it stand in our nosology. Diarrhœa is universally symptomatic of a great variety of diseases, many of which are different from one another; so that a genus formed from all these is a very complicated one, and comprehends many dissimilar affections and diseases." (First Lines, Dr. Thomson's edition, vol. ii. p. 470.) This observation of Dr. Cullen is very just; but he might have gone even further, and stated that in a perfectly philosophical system of medicine, what is commonly termed diarrhœa would be regarded merely as a symptom of different pathological states, and would, therefore, be banished from the list of individual diseases. We are, however, far from having attained to this perfection of pathology even in theory, and it is more than questionable if the adoption of such a view of the case in practice would ever be beneficial. The safer plan to follow is to consider the *flux*, termed diarrhœa, as a distinct disease, but to regard it as the consequence of various morbid states in different cases; the practitioner only taking care, before he applies his remedies, to ascertain the particular state which exists in the individual case before him, as far as his observation and pathological knowledge enable him to do so. If he does not do this, but regards the *flux* only, without reference to its cause, he will be liable to commit grievous errors in his treatment.

As a general rule, we may consider diarrhœa as having its seat in the intestinal mucous mem-

brane; and it is the state of this membrane, and not the discharge, which is to be regarded as the great object of attention to the pathologist and practitioner. The only exceptions to this rule are the cases where the disease is excited by fluids poured into the intestinal tube from the annexed glands, or by irritants of a temporary kind, as food or medicines, applied directly to the membrane. Even in these cases the secondary affection of the membrane is often of much more importance than the cause producing it.

In the class of cases just mentioned, the mucous membrane of the bowels can scarcely be said to be diseased; and the functional disturbance speedily subsides on the removal of the offending cause. But in the great majority of the cases of diarrhœa the membrane is affected in a more permanent manner, although the degree of this varies extremely.

In the mildest form of the affection there seems to exist merely a morbid degree of irritability, or a morbid sensibility, in the mucous membrane, which scarcely exhibits any indication of disease, except when excited by something applied to it. What, however, in a sound state would produce only the proper and natural degree of peristaltic action, now produces a morbid degree of action incompatible with perfect health. In another form of the affection there exists, perhaps in conjunction with the foregoing state, a morbid degree of excitement or of increased action in the membrane, considered as a secreting and exhaling organ, whereby it throws out its fluids in a morbid state or in a morbid quantity, or both. In a third class of cases it is supposed by some that the exhalents, in place of being excited to increased action, are in a state of atonic relaxation, and thereby allow their fluids to escape in a condition no less deviating from that of health.

But in a still more numerous class of cases there exists a more permanent deviation from the healthy condition of the mucous membrane, namely, some form or degree of that pathological state to which we give the name of inflammation. In diarrhœa this state may exist in every degree, from the slightest shade of congestive irritation up to well-defined alteration of the normal structure of the membrane: it may be confined to a small portion of the intestinal tube, or it may extend over a large portion. In this form of diarrhœa, the evacuations deviate greatly from the character of health, and consist principally of fluids secreted by the inflamed membrane, being mucous or serous, or flaky from admixture of coagulable lymph, and very variously coloured according to the condition of the liver, the ingestion of food, the previous treatment, &c. In almost all cases the inflammation is confined to the large intestines; but in some it extends to the small, and it may even originate there.

The form of diarrhœa just noticed, and which may almost always be regarded as present in recent cases of much severity, and in which the stools are not fecal, can be considered as differing from the disease termed dysentery only in degree. When the inflammation is strongly marked, no doubt there supervene some peculiar symptoms—particularly the intermixture of blood with the mucous discharges, and fever—which do not exist

in diarrhœa; but still the essence of both diseases is the same. Both are inflammations of the mucous membrane of the large intestines; but in the one the affection is slight, in the other it is severe. There is the same difference between them as there is between a mild pulmonary catarrh and bronchitis, but no more.

The diarrhœa which almost always attends the latter stage of phthisis depends on ulceration of the mucous membrane. The ulcers in this case are often extremely numerous, being spread over the whole extent of the bowels, but they are most common near the extremity of the ileum. Many other organic affections of the mucous membrane of the bowels, for the most part the consequence of inflammation, give rise to diarrhœa; but cases of this kind do not come properly within the scope of the present article.

The state of the mucous membrane found on dissection in simple diarrhœa, varies greatly in different cases. In recent examples, not connected with other diseases, opportunities for examination after death will rarely occur, as almost all such cases are cured. When opportunities of examination have been found, the membrane, in recent cases, has been observed more or less red and congested, or extremely pale and anæmic, the redness being disposed in patches or in continuous stripes, leaving the intervening portions very pale. In cases of more severity and long standing, although still short of the degree constituting the dysentery of nosologists, a great variety of morbid appearances have been found. In these the membrane presents every variety of colour, from the most intense red, purple, or brown, to the blanched or anæmic state above mentioned, in which there is nothing to be seen in the vessels but colourless fluids. In other cases there is an enlarged and patulous condition of the mouths of the mucous follicles, which look erected, and sometimes inflamed, and as if excoriated. The whole mucous membrane is also found thickened and œdematous, as in certain forms of dropsy, and is often greatly softened. The intestinal tube is frequently much contracted in its caliber. In some cases coagulable lymph is found adherent to the inflamed spots; but this is not of frequent occurrence: very tenacious mucus of an inspissated character is common. In many instances dissection detects scarcely any deviation from the state of health; and then we may reasonably suppose that the exhalents and mucous glands merely afford a rapidly increased supply.

The termination of diarrhœa, when unattended by other, and especially visceral diseases, is for the most part favourable. But when the inflammatory state of the membrane becomes considerable, the disease then, under the name of dysentery, may lead to very serious results, ulceration taking place in the different tissues of the intestine, sometimes followed by perforation and fatal peritonitis. In some cases the inflammation of the mucous membrane extends or is transferred to the serous coat, giving rise to ascites. In this way diarrhœa and dropsy have been observed to alternate, according as the morbid action chiefly occupied the internal or external tunic of the bowel. When it assumes the chronic form, diarrhœa is sometimes a most obstinate disease, resisting in many cases for

months or years, every variety of treatment. When, however, it is not immediately dependent on great organic changes in the bowels or connected viscera, the general health is often much less affected, even in severe cases, than might be expected. We have known chronic diarrhœas of considerable severity continue through the greater part of a long life.

**Treatment.**—In undertaking the cure of a case of diarrhœa, it is often of as much consequence to consider its degree of severity and its duration as its precise nature. Slight cases of every kind are in general easily removed; and in recent cases, even when severe, the mode of treatment is almost always simple, and generally successful.

*Acute or recent diarrhœa.*—1. In the common form of feculent diarrhœa recently produced by some known cause of irritation, as from improper food or otherwise, it is seldom that any other treatment is necessary except abstinence from food, with rest, and simple dilution. In such cases the offending matter is commonly itself speedily evacuated, and occasions at the same time a complete discharge of the whole fecal contents of the bowels. When this is effected, the morbid action usually subsides of its own accord, and health is at once restored. Sometimes, however, the offending matter is either not thrown off, or only partially, and a degree of excitement is kept up sufficient to irritate the bowels without unloading them; the stools, partly fecal, partly mucous or serous, are scanty, and are accompanied with more or less of griping. The indication here evidently is to unload the bowels thoroughly; and it is best fulfilled by an active but not irritating purge, such as castor oil, rhubarb and magnesia, or the common senna draught of a moderate degree of strength. When the evacuations are free and complete, the irritation is commonly at an end. But sometimes, in place of being insufficient, the evacuations are too copious; the irritating matter has acted like a drastic purge; or the ineffectual efforts produced by the primary cause have been raised beyond the healthy degree by the purgative, and the same result of hypercatharsis ensues. In cases of this kind the obvious and appropriate remedy is an opiate; and few cases will resist the effect of this when combined with quiet, a warm bed, and abstinence.

In feculent diarrhœa coming on without any very obvious exciting cause, in persons who are great eaters, or whose bowels are generally in a confined state, it will likewise be proper in most cases to administer a purgative, as the probability is that the cause of the diarrhœa is some irritating matter lodged in the bowels, and not any primary source of irritation in the intestinal membranes; and it may be stated, as a general rule, that in recent cases, if the motions are fecal, this practice will always be safe, and generally beneficial. Even in cases where the stools are altogether without proper fœces,—mucous or serous,—if there exist any reason to expect an accumulation of feces in the bowels, a purgative will still be proper. The previous health of the patient, his habits as to eating and alvine excretion, the nature of the stools at the very commencement of the attack, and the degree of tension and hardness of

the bowels, will, if duly weighed, in most cases lead to a just conclusion as to the point in question. Where there remains any doubt, the safest plan will be to give a moderate dose of a mild purgative, particularly castor oil, and be guided by its effects. If by its operation fecal stools are brought away, and the irritation still continues, a repetition of the dose or a still more active form of medicine will be proper. In persons whose bowels have been costive for some time before the attack, and also in those who are large feeders, and particularly if they lead sedentary lives, a dose of colocynth with calomel and antimonial powder may be proper, followed up after a few hours by the saline senna draught; the after treatment being the same as before.

2. If the feculent diarrhœa is complicated or caused by a superabundant secretion of bile, it will be necessary to restore the liver as well as the bowels to its healthy functions. The unloading the bowels by purgatives may be at first necessary; but when this is effected, the treatment of the hepatic affection may be a work of some time. It is obvious that the consideration of this subject belongs rather to another place, (see HEPATITIS, and LIVER, DISEASES OF); but we may be allowed to say a few words on it in reference to diarrhœa. If the augmented flow of bile or its depravation has been produced by a mere temporary excitement, little specific treatment will be requisite, as the disorder of function will in most cases be removed on the removal of the cause. What is more commonly called bilious diarrhœa is, however, in general, an affection of a more fixed character, depending, as we had occasion formerly to remark, either on an inflammatory state of the liver itself, or an excited condition of this gland transmitted through its ducts from an inflamed duodenum. In both cases the disease is usually of an acute character, and requires nearly the same treatment. If the inflammatory state is considerable, or is attended with fever, venesection will be proper; but this will not often be the case in any state which can be classed under the head of diarrhœa. Local bleeding with leeches, or cupping in the hepatic and præcordial region, will, however, always be proper, and must be carried to such an extent as the urgency of the symptoms may seem to require. The repetition of this measure several times, after the interval of one or two days, may be requisite; and its effects will be greatly promoted by the frequent use of warm fomentations to the same parts. Mild mercurial preparations, the best of which is the hydrargyrum cum cretâ, will also be proper in cases of this kind, more especially if the affection of the liver is primary; they should be given in small doses at bed-time, and followed up next morning by a moderate dose of castor oil or other mild purgatives; but care must be taken that the inflammatory condition of the duodenum (if it exist) be removed, or at least mitigated by other means, before the administration of purgatives. Calomel will then have a much more beneficial effect in restoring the healthy condition of the liver. Cooling, saline, and demulcent ptisans constitute the best general remedies in this kind of diarrhœa, and commonly suffice, in conjunction with the means above mentioned and a proper

diet, to restore the patient to health. The proper diet in these and other cases will be mentioned hereafter.

3. In the acute or recent diarrhœa, distinguished by the discharges being chiefly mucous or serous, with little or no admixture of proper fœces, all these having been previously evacuated either by the natural efforts or by purgatives administered with this intent, we are no longer to look for relief from the employment of cathartics, but from means calculated to allay the irritation which exists in the mucous membrane, and which constitutes the disease. These means consist of a proper diet, or the abstinence from all food, the internal use of refrigerants, diluents, demulcents, diaphoretics, and opiates, the local detraction of blood, warm baths or fomentations, and other measures of analogous tendency. The treatment will vary considerably according as the attack is slight or severe, and also according to the nature of the exciting cause. In very mild cases, keeping the patient in bed, and restraining him from the use of all kinds of food, with the exception of barley-water,—in small quantities, and this only if there is thirst,—will very often put an end to the attack in twenty-four hours, without any other means. If the attack appears to have originated in cold or obstructed perspiration, it will be proper to apply the general means found most useful in catarrhal affections, of which the most effective are confinement to bed, in a warm room, and mild saline diaphoretics. If the case is somewhat more severe, the application of warm fomentations to the abdomen, by means of flannel bags filled with bran and dipped in hot water, will be proper, (they will indeed be proper, though perhaps not absolutely necessary, in the very mildest cases,) together with small doses of mucilage, with or without nitre or the liquor ammoniæ acetatis, and an equally rigid system of diet. If the diarrhœa does not speedily yield to these mild measures, or if it be accompanied with much griping or painful tenesmus, a small dose or two of laudanum, or of the pulv. ipec. comp. in chalk mixture, will be proper; or a glyster may be administered, consisting of not more than a couple of ounces of starch mucilage, and a proportion of opium varying according to the severity of the case.

When irritation is not very considerable, these means will almost invariably put an end to the attack in a very short time. But should they not do so, or should the severity of the symptoms at the commencement announce the invasion of a more formidable disease, previously to the use of opiates, six, eight, ten, or twelve leeches, according to the violence of the attack, should be applied to the anus, and the glyster be afterwards given. The leeches may be applied a second or even a third time, if the complaint proves obstinate. In some cases general bloodletting may be proper; but this is a measure rarely necessary while the disease remains of such moderate severity as still to justify the application to it of the term diarrhœa.

The internal remedies we are accustomed to employ in the cases where opiates are improper or unnecessary, or in conjunction with these, consist almost entirely of the blandest fluids given in small quantities, such as the mucilage of acacia

or tragacanth and water, with or without nitre; the chalk mixture with the same substances, small doses of the liquor ammoniæ acet., and the like. Indeed, were it not that it is often necessary, for the satisfaction of the patient or his friends, to administer some medicine internally, the case would often be better left to nature, after the employment of the more active remedies; but if medicines are given, they should be such as are at least harmless. We will venture to assure the inexperienced that they will find such means infinitely more conducive to the recovery of the patient, in the cases now under consideration, than either purgatives, or astringents, or opiates, which we regret to say are so often lavished by those who in their pride of *bold practice*, as it is termed, are accustomed to regard with scorn the treatment we are now recommending. When the disease is prolonged beyond the space of twenty-four or forty-eight hours, or even during this period, if desire for food is urgent, more nutriment may be allowed; but this must be in very small quantity, and either liquid or of the softest deliquescent solids. Of this kind are barley-water, rice-water, arrow-root, sago, weak tea with milk, rice-gruel, weak chicken or veal broth thickened with rice or barley, &c.

In the variety of mucous diarrhœa which occurs in certain epidemic constitutions, and in persons of a sluggish phlegmatic habit, and in which the intestinal tube is rather irritated secondarily by its own morbid secretions than primarily, a different kind of treatment is necessary. Both emetics and purgatives are here indicated; the first to evacuate the contents of the stomach and to stimulate its coats to more healthy action; the last to produce a similar effect on the bowels. Ipecacuan is the best emetic in such cases, and the same medicine, in small quantity, will be very properly combined with rhubarb as a purgative. A useful purgative will also be found in small doses of castor oil combined with a few drops of the ol. terebinth. When by these means the bowels are unloaded of their morbid secretions, and the membrane stimulated to more healthy action, if the diarrhœa still continues it must be checked by mild astringents and tonics, or by small doses of opium. In these cases catechu and kino are found useful; but when such means are necessary, the disease will come under the head of chronic diarrhœa, the treatment of which we shall now notice.

**CHRONIC DIARRHŒA.**—This form of diarrhœa is that which the practitioner is most frequently called upon to treat, and which he finds by far the most difficult to cure. In addition to the intrinsic severity of the disease, sufficiently evidenced by its long duration, and perhaps in spite of proper treatment, he has probably to contend against many obstacles to recovery which did not exist, or existed in a much less degree, in the acute disease. The patient may have probably an excellent appetite, and cannot or will not refrain from food calculated to keep up his complaint; neither can he be restricted in many other particulars which obstruct recovery, but which the violence of the acute disease either forced him to attend to, or its brevity rendered but little irk some.

Chronic diarrhœa may assume all the forms of

the acute variety as far as regards the nature of the evacuations, and most of them may successively appear in the same case; although, generally speaking, the motions preserve one predominating character, as in the acute disease. It is chiefly in the chronic form, however, that the food appears undigested in the stools; a circumstance readily accounted for both by the nature of the two cases and the diet respectively used in them. In many cases of diarrhœa which are chronic both as to time and the moderate severity of the symptoms, the disease is found, on close examination, to consist rather of a frequent return of slight attacks of the acute kind, than to be strictly chronic, in the usual sense of that term. This is an important distinction, and deserves the best attention of the practitioner.

In respect to the treatment of chronic diarrhœa, it may be stated generally, that when the symptoms assume the general character of any of the forms of the acute disease formerly noticed, the treatment to be had recourse to must be similar in kind, but modified by the degree of severity and other circumstances of the particular case. Other modes of treatment will, however, be often necessary, and which would have proved injurious in the acute affection. It is here where the medicines properly termed astringents, and also tonics, are applicable, and which are so seldom proper in any of the acute forms. In numerous cases of the chronic disease such remedies are likewise very improper, and we believe that the great art of treating chronic diarrhœa successfully, consists principally in the practitioner having the skill to discriminate such cases as are benefited by purgatives and astringents, from the very large proportion which are injured by them.

We think it will not be disputed by any practitioner of experience, who has been accustomed to consider diseases more according to their pathological relations than as mere subjects of empirical prescription, that the greater number even of chronic diarrhœas depend not so much on any foreign matter applied to the intestinal mucous membrane, as on some intrinsic irritation of this membrane itself; and, consequently, that the treatment in all such cases is founded not on the indication of evacuating irritating matters, but on that of allaying organic irritation. In a certain proportion of cases, no doubt, such irritating matters are present, and their evacuation is essential to the cure of the disease. Great mischief, however, has arisen from the false notion entertained by many practitioners in this country, that *most* diarrhœas are occasioned by such extraneous sources of irritation, and which can only be relieved by purgatives. We cannot too strongly enter our protest against such a principle as a general rule of practice. The circumstances under which purgatives may be used in recent or acute cases were formerly pointed out; and when similar circumstances exist in the chronic stage, the same treatment will be proper. The accumulation of feces in the bowels in conjunction with diarrhœa, will always indicate the propriety of purgatives, and they may, in a general way, be considered as not likely to be injurious as long as the stools are feculent. The same observation is equally applicable to those cases in which there appears to be a morbid accu-

mulation of mucus or other secretions in the intestinal tube.

We do not mean to deny that even when the disease consists essentially in an irritation of the membrane, a purgative may not lessen or relieve it; indeed, we know by experience that this is actually the case, and it is only what might be expected from the known effect of stimulant applications to chronic inflammations of other mucous membranes; but we wish the young practitioner to understand that this practice is to be considered as the exception, not as the rule in the treatment of diarrhœa, and that even when a purgative has relieved the symptoms, it is not to be hastily or often repeated. The repetition of purgatives in all bowel complaints requires much judgment and discretion. Aperients may be considered as fairly applicable in cases in which the irritation is of an inactive kind, or where the disease has proved rebellious to remedies of a different class. In such cases rhubarb is perhaps the best purgative.

Another notion, no less false, and perhaps even still more prevalent among practitioners, is, that a great proportion of chronic diarrhœas depend on debility or loss of tone of the intestinal membrane, and are only to be relieved or removed by astringents, tonics, &c. Such a state may undoubtedly exist; but we are well assured that the number of chronic diarrhœas which originate in this cause is extremely small compared with the cases which depend on an irritated or inflamed state of the membrane.

On the whole, we wish the young practitioner to understand that he is to proceed to the treatment of chronic diarrhœa on the only rational principle of endeavouring to ascertain the precise nature of each individual case before he prescribes for it; that he is to give emetics or purgatives where there is evidence that the bowels are oppressed or irritated by fecal accumulations or morbid secretions; that he is to give astringents and tonics where the flux seems to be the consequence of a debilitated and relaxed state of the mucous membrane; that he is to soothe excessive irritability by opiates; and that he is to remove congestive irritation and inflammation by the means best calculated to effect this object in other parts of the system, namely, by removing all causes calculated to keep up irritation, and by the employment of such means as have the power of directly diminishing the local disease. Our limits will not permit us to enter into the consideration of the characteristic features of each of these different kinds of diarrhœa; but their discovery will not be very difficult to any one who is well grounded in the general principles of pathology, and who will take pains to investigate with attention the history and phenomena of the different cases that come before him.

[Attention has been drawn by Dr. Stokes (*Lectures on the Theory and Practice of Physic*, 1st Amer. edit. p. 87: Philad. 1837,) to a chronic form of diarrhœa, depending upon ulcerations of the rectum, at a short distance from the anus, which may be seen with the aid of the speculum. They occur chiefly in those of broken-down constitutions, and in such as have taken a great deal of mercury. The symptoms are—irritation of the colon, tenesmus, tormina, frequent evacuations

and generally, during the straining, a little blood is passed. Dr. Stokes advises, that the rectum should always be examined, when diarrhœa has been of long standing, has resisted a great variety of treatment, has been combined with tenesmus, and a desire to remain on the night-chair after an evacuation,—which shows irritability of the lower part of the tube; and when the health does not appear to be so much affected as it naturally should be where there has been long-continued disease of a large portion of the great intestine. Since the writer's attention has been directed to this pathological cause of chronic diarrhœa, he has met with several cases, which have been treated successfully by touching them, where practicable, with lunar caustic, or by a strong solution of nitrate of silver—from four to twenty grains to the fluidounce of water.]

We shall conclude this article by some further observations on the principal remedies used in diarrhœa.

**Diet.**—In all the forms of diarrhœa, acute or chronic, and whatever be the other kind of remedies which are proper, there is one mode of treatment which is universally applicable, and which is the most important of all: this is a proper system of *diet*. This is so important a part of the treatment, that we have no hesitation in stating that the majority of cases of diarrhœa, both acute and chronic, that are curable, may be cured by it alone. In all cases of acute diarrhœa, and in the large class of chronic cases which depend on irritation of the mucous membrane, the food should be very sparing in quantity, of the mildest quality, and such as to leave, after the process of digestion, as little excrementitious matter as possible. In recent attacks of the acute diarrhœa, it is often proper to take no food for the first day, or only mild drinks, containing a small quantity of unirritating nutriment, such as barley-water or arrow-root. During the subsequent days, the same general kind of diet must be continued, but may be given in larger quantity or of greater strength. When the irritation is somewhat allayed, on the third or fourth day perhaps, but not earlier, broths may be allowed, but no solid food of any kind, and, least of all, solid animal food is to be permitted, until the disease is removed or greatly allayed.

The following may be stated as the order in which the articles of diet will generally be found most proper in such cases: barley-water, arrow-root made with water, sago or tapioca, rice-gruel, oatmeal-gruel carefully strained, light broths, with some of the preceding ingredients. In some cases, more especially the chronic kind, a drier diet is found more suitable,—the liquid food appearing to keep up the diarrhœa; but in all cases the ingesta must be of the mildest quality. Rice is one of the most valuable articles of diet in such cases. It should be well boiled and merely moistened with a little broth. While it is extremely mild and unirritating, rice scarcely leaves any remains to be transmitted along the intestines, and this is the reason why it is generally regarded as astringent. As soon as it can be borne, a *small portion* of the lightest animal food may be taken with the rice. Tender chicken is the best to begin with; then white game boiled; and then

roast mutton. The meat of young animals, as lamb and veal, should be avoided. Beef is too stimulant, and fish is bad on account of the large quantity of excrementitious matter it leaves in the bowels. Animal jellies are generally allowable in the case where meat is found to agree; but they often are more irritating to the bowels than the muscular flesh of animals.

In chronic diarrhœa attention to diet is no less necessary, and in general it will be found that the same kind of food is alone proper. It constantly occurs to us to meet with cases of diarrhœa of many months' standing, or which have lasted even for years, and which are speedily removed by the substitution of a mild unirritating diet for the ordinary food of healthy persons. We will here give the outlines of a recent case of this kind, extracted from the out-patients' journal of a public institution to which the writer is attached, and we introduce it the rather because it is *not* an uncommon case.

May 4, 1821. J. G., gardener, æt. 35. Has been affected for two years with his present complaints, which constitute that form of diarrhœa commonly termed *lientery*. During the whole of the above-mentioned period he has had five or six loose stools daily. He has a good, often a craving appetite, but unless he is very particular as to what he takes, he suffers pain, sometimes severe pain, shortly after eating, and a relaxed motion speedily follows. The stools are in general liquid, slimy, dark, and offensive, and frequently contain masses of undigested food. All sorts of hard or solid food disagree, such as tough meats of every kind, pork, cheese, &c., and when taken, appear unchanged in the subsequent motions. More fluid food agrees, such as arrow-root, gruel, rice, broth if not fat, &c. He is much troubled with flatulence, but is never sick at stomach so as to vomit, nor is he thirsty. The tongue is white, with considerable tenderness on pressure, and also distension of the epigastrium; the urine is clear. There is no particular dryness of skin, and he perspires easily on exertion. He has occasional headache, giddiness, and slight palpitation, and the feet are often cold especially at night. He sleeps well, except when pain is present in the bowels. He has lost eighteen pounds in weight during the last twelve months. Notwithstanding the avowed inconvenience produced by certain kinds of food, he does not usually debar himself from them. He also drinks beer, about two pints daily.

This man was directed to alter his diet entirely; to give up all kinds of solid food, and to live on broth, jellies, light puddings, rice, and liquid farinaceous food; to give up drinking beer; and, in a word, to take nothing which he knew to have the effect of irritating his bowels. He was directed to put his feet in warm water every night. The only remedies prescribed were, ten leeches to the pit of the stomach, and a powder consisting of pulv. tragacanth.  $\mathfrak{z}$ ij. potassæ nit.  $\mathfrak{z}$ j, to be dissolved in half a pint of cold water, and taken daily in divided portions.

The effect of this change of regimen, (to which the man adhered faithfully) was, that the diarrhœa ceased within three days, and never returned. He was not, however, discharged from the books of the infirmary until the end of July, æt

though he had for some time returned to the use of animal food without suffering any inconvenience: indeed, he said his bowels were then in a better state than he ever remembered them to have been. This man continued well many months after his discharge.

In some cases of chronic diarrhœa, however, particularly those in which astringent medicines are found useful, a solid diet of a more stimulating quality, with a moderate proportion of wine, is found much more useful than the bland unirritating food above mentioned. In such cases the dry and tonic diet has the effect of producing motions of a more solid kind; while at the same time it tends at once to restore the lost tone of the bowels and the general strength. In practical medicine we must never follow our pathological principles so far as to be blind to the results of experience; and in diarrhœa, as in every other disease, however we may allow to science the initiatory in prescription, it is the observation of a favourable result alone that can justify perseverance in any kind of regimen or medicinal treatment.

*Leeches.*—In the case above detailed we are disposed to attribute nearly all the good effects to the change of diet; but the application of leeches, even for a single time, was probably of benefit. We judge so from the marked benefit we constantly find from their use in this complaint, whether in the acute or chronic form. When the diarrhœa is evidently complicated with a state of irritation or slight inflammation of the mucous membrane of the stomach and small intestines, the treatment should begin with the application of leeches to the epigastrium. If this and the appropriate diet fail, then leeches must be applied to the anus, or to this part in the first place, if the diarrhœa is uncomplicated with gastric irritation. For the relief of the inflammatory irritation of the large intestines, there can be no doubt that leeches applied to the anus are greatly more efficient than when placed on the abdomen. This remedy is indeed possessed of remarkable powers in the disease, often working, according to the common expression, “like a charm,” even in cases of very long standing and of different external characters. Combined with proper diet, indeed, we are persuaded that the greater number of diarrhœas, both acute and chronic, will yield to this method, with little or no aid from other medicine. We have repeatedly known a diarrhœa of long standing, more particularly in the case of infants, cured by a single application of two or three leeches only; and in more obstinate cases it will be found that an instantaneous and marked remission of the symptoms follows every repetition of the remedy. Although, in our own practice, we always combine with the use of leeches, in the cases where they are indicated, a proper diet, yet we have had ample evidence of their unassisted powers in checking or removing diarrhœas of great severity and obstinacy. We would add one caution, which may be useful to those not in the habit of making much use of this remedy:—to ensure the full effect, the leeches should be applied immediately to the anus, that is, as close to the mucous membrane of the extremity of the rectum as possible. Unless accurate directions are given,

nurses will be apt to mistake our meaning. It has frequently happened to us to find the prescription of *hirudines* *ano* carried into effect by their being applied to the buttock, perineum, or even sacrum.

*Bathing.*—In most of the cases in which an unirritating diet and the local detraction of blood are beneficial, the employment of some form of the tepid or warm bath will be useful. Although the general bath is often indicated, and is the best form of the application, yet in the majority of cases we find that the frequent use of warm fomentations to the bowels by means of flannel bags of bran, with the foot-bath at bed-time, answers completely in promoting the removal of the intestinal irritation. (See BATHING.)\*

*Opiates.*—Of the means calculated to assist in the cure by affording temporary relief from pain, as well as by directly allaying the irritated condition of the bowels, no remedy equals the use of opiate injections. In all cases where there is tenesmus with pain and frequent stools, this remedy is to be had recourse to as a means of temporary relief, whatever other plan may be pursued for the permanent cure of the disease. Solid opium, or extract of poppy, carefully rubbed down into mucilage, or the pulvis opii, Battley's liquor, or the common tincture, may all be used. Perhaps the pulvis opii is, on the whole, the most convenient form; of which one, two, or three grains may be administered in a couple of ounces of starch mucilage. This may be repeated according to the urgency of the case; but the student is to be earnestly cautioned not to be seduced by the relief often produced by this application, into the neglect of means of more permanent efficacy.

*Astringents.*—It will not, we trust, be imagined, from the manner in which we have recommended the use of the foregoing remedies, that we consider the treatment of diarrhœa by the use of astringent medicines, properly so called, as generally either useless or improper. On the contrary, we know that cases of this disease are every now and then met with, that can only be cured by such medicines; and that they are very often necessary, at least as palliatives, in the chronic form of diarrhœa. Sometimes nothing else affords relief. All that we labour to impress on the mind of the young practitioner, or on those who have unfortunately been taught to treat diseases as mere collections of symptoms, without reference to pathology, is, that there are many kinds of diarrhœa which can be best treated without astringents and without purgatives; and that the presence of frequent fluid dejections does no more necessarily indicate the use of such remedies, than any other single symptom necessarily indicates a peculiar treatment, without reference to the whole disease of which it is but a part.

In all cases, before we have recourse to astringents, the state of the patient must be carefully examined into, the nature of the evacuations, the state of the abdomen, &c.; lest some inflammatory affection should still remain and keep up the

\* Riverius gives his own case in testimony of the efficacy of the warm bath in diarrhœa. “Corruptus sum diarrhœa biliosa, tanta acrimonia prædita ut anum eroderet, ardoremque urine concitaret. Dysenteria erat in prociuctu. Ingressus semicupium tepidum, illico liberatus sum.—River. Op. Univ. p. 599.

the diarrhœa. Astringents are a class of remedies which seldom fail to do mischief when they do not do good. They are indicated in the cases where the diarrhœa appears to be kept up by loss of tone, or by a morbid degree of irritability, not dependent on vascular orgasm or inflammation, in the mucous membrane of the bowels; and they are properly used in all chronic cases which have resisted the means calculated to relieve active irritation, or other known pathological conditions, as noticed above.

For the particular forms of astringents most useful in such cases we must refer to writers on *Materia Medica*, and to the article *ASTRINGENTS* in the present work. We can only afford space here for a few observations.

The astringent substances from the vegetable kingdom that have been used in alvine fluxes are extremely numerous; and it is probable that some of those not now included in our pharmacopœias, or, if included, not much employed, are not the least useful. Catechu and kino are now in most common use, probably not so much because they are in reality the best remedies, as because they are the strongest astringents. They are, however, often very useful in the cases of diarrhœa wherein remedies of this class are indicated. Both these substances may be given separately, or in combination with opium or other astringents. One of the most usual forms of prescription is the tincture of catechu in chalk mixture, combined with equal parts of the tincture of cinnamon. In other cases the watery infusion of catechu answers better, in the form of the *infus. catechu comp.*, and may be given in doses of one or two ounces after every loose motion.

Dr. Pemberton had an idea that kino had some peculiar virtues as an astringent; that it did not act as such except diarrhœa were present. He therefore gave it the preference to other astringents. His mode of administration was in doses of a scruple made into a bolus with opiate confection. (*Treatise on Diseases of Abdom. Visc.* pp. 112 and 149.) More recently an extensive series of experiments on the effect of kino in diarrhœa, were made in the hospital of *La Pitié*, in Paris, by M. Bally. In chronic diarrhœa, unaccompanied by fever or marks of inflammation in the mucous membrane, the continued use of the remedy, even for a short time, was found almost invariably effectual in stopping the diarrhœa. In one case of three years' standing it effected a cure. But the most remarkable result of M. Bally's experiments is the alleged fact—that the kino, given in doses of twelve or fourteen grains for several days in succession, succeeded in curing diarrhœas attended by febrile and inflammatory symptoms. (*Med. Gazette*, vol. v. p. 700.) We confess we are surprised at such a result.

Logwood, tormentil, and bistort were more employed formerly than at present as astringents. We believe the former to be a valuable remedy: the best form of using it is decoction, which may likewise be made the vehicle for more active remedies. The plantain (*plantago*) was much used by the older authors; and it and many other vegetables were taken boiled in broths and demulcent pisans—a form of medicinal administration too much fallen into disuse in this country. Un-

ripe medlars were formerly famous for their occasional effects in diarrhœa; but we apprehend the cases are few in which they can be recommended.\*

Among the mineral astringents, lime and its carbonate deserve attention, as being in most common use, and as being perhaps not the less useful because they are possessed of only moderate astringency. In certain mild forms of diarrhœa, particularly after the use of purgatives, the *pulv. cretæ comp.*, with or without opium according to circumstances, is a very mild and valuable remedy; and the *mistura cretæ*, it need hardly be said, is the common and one of the best vehicles for other more powerful astringents. In the more chronic forms of diarrhœa lime-water has been found occasional useful, taken in large quantities as a beverage; and it is very properly combined in such cases with gum, and often with milk. Equal parts of lime-water and milk, with acacia or tragacanth, is a favourite remedy with many old practitioners. Alum is a medicine given frequently in a somewhat similar form, under the name of *alum whey*, which is made by adding two drachms of the alum to a pint of boiling milk: of this whey a glassful or three or four ounces may be taken as a dose. Alum is also given in a solid form, in bolus or pill, combined with kino, catechu, or opium. The stronger mineral astringents, the acetate of lead and sulphates of copper and zinc, are occasionally useful, particularly the sulphate of copper; but this remedy is chiefly applicable in a form of the disease which does not come properly under our notice in this article, the diarrhœa of phthisis.

[The solution of persesquinitrate of iron and the tincture of chloride of iron are said to have succeeded when other remedies had failed. (See the writer's *New Remedies*, 4th edit. p. 294: Philad. 1843, in regard to the former.) The *artemisia vulgaris*, *carbo animalis*, and *ferri ferro-cyanuretum* have been recommended of late years; but there is no reason for believing that they are superior to other vegetable and mineral tonics.

Of late, a mixture called *Hope's Mixture*, from its proposer, which consists of nitrous acid and opium, forming a nitrate of morphia, has been highly extolled, in the United States more especially; but it has not succeeded more frequently with the writer than other remedies suggested by the nature of the case. It is composed as follows: *R. Acid. nitros. f.ʒi; Aquæ camphor. f.ʒviij; Tinct. opii gt. xl.*—*M.* Dose, a fourth part, every three or four hours.

The balsams and turpentine have been much prescribed. Of these the copaiba and the oleum terebinthinæ are alone employed at the present day. *Nux vomica* and its active principle have,

\* Forestus relates a case of diarrhœa which seems to have been most particularly obstinate, since he informs us that the poor patient "*omnem suam substantiam frustra in medicorum ope consumperat, consilii causa, ut ab hoc malo liberari posset*," but which he (Forestus) cured in a few days by giving him a great quantity of unripe medlars to eat. The same author tells us of a patient of Spirinchius, who was cured of an equally obstinate diarrhœa by the same means; but Spirinchius was more fortunate in a richer patient, "*qui medicæ trecentos aureos pro sola spirinchii præscriptione numeravit*." Forest. Op. tom. iii. p. 47.

likewise, been used, and occasionally with great advantage.]

In this and other forms of diarrhœa depending on disorganization of the bowels, opiate clysters are commonly found most effectual. A simple form of injection recommended by Van Swieten is also found occasionally beneficial in this distressing complaint: it consists simply of an ounce of treacle or juniper-rob in three or four ounces of warm milk. (Comment. vol. ii. p. 394. *Diarrhœa Febrilis*.)

In every form of chronic diarrhœa, warm clothing with flannel next the skin, and an additional quantity on the abdomen, in the form of a belt or swathe, is highly useful. In many cases, also, warm galbanum plasters and other warm external applications to the abdomen are very beneficial. This mode of treatment was much used by the older authors. (See *Forestus passim*.)\*

It is hardly necessary in all such cases to dwell on the propriety of the patient being lodged in a dry well-ventilated chamber; or of the advantages of a mild and dry climate. Chronic diarrhœa is, indeed, one of the diseases in which a change to a warmer and drier climate than ours is found most beneficial, (see CLIMATE); and this leads us to notice the fact well known to travellers, and to physicians who have had much to do with travelling invalids, that a journey is almost specific in arresting diarrhœa.

JOHN CRAMPTON.  
JOHN FORBES.

ADIPOUS DIARRHŒA *molten grease*, the *gras fondure* of the French, is characterized by a discharge of fatty matter from the bowels, sometimes in a fluid state, at others in the form of fatty concretions. Many cases of the latter are recorded; and, of late years, attention has been especially directed to the former. In one case related by Sir Everard Home, the fatty discharges might be accounted for by the patient's habit of taking castor oil regularly; but in other cases, the adipous discharges are evidently at the expense of the system.

At times, the discharge is in the form of oil, or semi-concrete matter floating on the top of the feces, and possessed of a fetid odour. The quantity evacuated differs greatly. In one case, which occurred to Dr. J. B. Jackson, of Boston, it amounted on the average, in twenty-four hours, to about eight ounces during more than four months.

Some fatty concretions, analyzed by Lassaigne and L. Gmelin, had the following constituents: seventy-four parts of an acid fatty matter, in which stearin predominated, elain and a peculiar acid; twenty-one parts of a substance analogous to fibrin; four parts of phosphate of lime and one part of chloride of sodium. In another case, there were, in one hundred parts, sixty of matter similar to spermaceti; thirty of phosphate of lime; eight of animal matter, and two of loss.

In many of the cases of fatty discharge, there was concomitant disease of the liver, pancreas or duodenum; so that it was imagined the abnormal

secretion might be the product of the pancreas or the liver. On the other hand, in some of the cases on record, the ducts of the liver and pancreas have been so obstructed as to preclude the idea of its being the product of either of these viscera; and moreover it has been seen in cases in which there was no reason to believe in the existence of serious disease of those organs. At the age of three years, a little girl was observed to discharge something from the bowels as she walked across the room; this, when examined, was found to be fat in a liquid state, which concreted when cold. "Ever since that time to the present," (a period of eighteen months,) "she has voided," says Dr. Babington, — the respectable narrator of the case, — "at intervals of ten or fourteen days, the quantity of from one to three ounces, sometimes pure, at others mixed with the feces: when voided, it has an unusually yellow tinge, and is quite fluid, like oil. Her appetite is good, as well as her spirits, and her flesh firm, her belly rather tumid but not hard." In other cases, the disease appears to have occurred during phthisis, hysteria, and other affections; in some instances, oil was discharged from the bladder likewise, and fatty concretions have been taken from the vagina. One of these was examined chemically by Dr. Martius, jr., and found to be composed of fat with some traces of salts.

These facts sufficiently establish, that under certain circumstances, and, doubtless, under the influence of particular diseases of the neighbouring organs, the gastro-enteric and other mucous membranes may secrete fat from the blood, as the physter macrocephalus occasionally secretes an enormous quantity of fat under the form of ambergris: — as much, it is asserted, as one hundred and eighty-two pounds have been found in the body of one of these animals.

**Treatment.** — Where organic disease exists, the efforts of the practitioner may be fruitless; but where the affection consists of a vicarious secretion from the mucous membrane of the intestines, it may admit of cure. The best mode of management would seem to be, to attempt a thorough revolution in the whole system of nutrition by change of diet, and an entire mutation of all the atmospheric and other influences surrounding the patient. Mercurials and other agents belonging to the class of eutrophics, — iodine, and its various preparations, for example, — may be serviceable in this view; and we may be able to comprehend, that new impressions made on the nerves by the various remedies recommended in hysteria, may put an end to the adipous secretion in hysterical individuals, by removing the irregularity of the nervous and other functions, which constitute that protean malady.

ROBLEY DUNGLISON.]

**DIETETICS.** — An organised body, whether of the animal or vegetable kingdom, cannot sustain the functions of life without a certain expenditure, or consumption of the materials of which it consists; and it is evident, therefore, that every living being, in order to continue its existence, must possess the means of receiving and assimilating to itself foreign matter for the repair of its diurnal waste. It is upon this necessity that the want of food is founded; its judicious administra-

\* Quibus adjungenda sunt *topica*, olea, unguenta, linimenta et fotus, unguenta et irrigationes, ex oleo omphac. rosaceo, myrteo, cotoneorum cum vino adstringente. cerata, &c. Forest. vol. iii. p. 58.

tion must be directed upon principles the knowledge of which can be alone derived from the sources of physiology and chemistry.

The possession of a receiving canal, or internal cavity of some kind, would appear to be exclusively characteristic of the animal creation; and Cuvier has distinctly stated that he knows of no animal unprovided with such an apparatus. In plants, on the contrary, which never contain any organ analogous to an internal stomach, the fluid supplies are absorbed by pores on their surfaces; and although some physiologists have questioned the propriety of so sweeping a generalization, minute investigation has shown, that so far from being real, the instances adduced by them in support of their objection are only apparent exceptions to this general law of nature. To enter upon this wide field of inquiry would be altogether foreign to the practical objects of the present article; nor can we undertake to examine the great diversity of means which Nature employs in the different orders of animals for the conversion of food into nourishment or into blood; we shall only observe that with such nicety are the processes of waste and supply adjusted, that whatever may be the quantity of food taken, or however the circumstances under which it is consumed may vary, the same individual, after having augmented in weight in proportion to the quantity of ingesta, will return in the space of twenty-four hours to nearly the same standard, provided the development of growth, or the existence of disordered function, does not interfere with the result. During this period, the food has been decomposed, and re-combined into compounds analogous to those which constitute the organs to which it is carried; and this would appear to take place, however remote its composition may be from that of the structures with which it is assimilated. It is, however, important to notice that the extent of the digestive cavity bears a relation to the nature of the food it is destined to receive, and by which the animal is designed to be nourished; for the more dissimilar its composition to that of the body it is to recruit, the longer must it remain in its alimentary cavity, and the more complicated must be the changes which are to perfect its transmutation. We thus find that carnivorous animals have generally less capacious and complicated organs than the herbivorous tribes; and that amongst the latter, those that feed upon seeds or fruits, with the exception of the *ruminantia*, have them less so than those which live upon leaves or the entire vegetable. The digestive canal of man is less capacious and complex than that of other mammalia which live entirely on flesh; whence we may infer that in a state of nature he may be capable of subsisting either on animal or vegetable food, and that he is not only qualified for every diversity but for every admixture of it. Thus do we see that, while many savage tribes exist almost entirely on fruits and roots, others are as exclusively fed on raw animal flesh. The Hindoos, for instance, live upon rice; the Lombard peasants upon maize; the West Indian negroes fatten upon sugar, those of Senegal upon gum; while the Esquimaux gluts himself with the blubber of the seal. It would appear, however, that although man may subsist upon almost every variety of

food, he cannot bear with impunity a sudden transition from one species to another. This circumstance was well exemplified in the eastern part of France in the year 1817, where the failure of the crops occasioned such a famine that the poor were compelled to feed upon whatever vegetable productions could be found: the consequences are stated to have been general anasarca, interruption of the menstrual discharge, a diminution of the ordinary number of conceptions by at least one half, and a permanent injury to the health. Even the sudden return to the use of barley bread, after the continuance of this miserable regimen for three months, M. Gaspard informs us, was not unattended with danger. Spallanzani has satisfactorily shown that animals may be brought to live on food of the most opposite kind, provided the change from their usual diet be *gradually* accomplished,—such, for example, as a pigeon on flesh, an eagle on bread, &c. We know that in certain maritime districts of the East, horses are not unfrequently fed upon fish, while on the coast of Coromandel they are fattened upon balls of boiled flesh mixed with grain; and it is on record that a lamb kept on ship-board was fed with flesh until it refused the grass when afterwards turned into a meadow. Such facts have induced some physiologists, amongst whom we may mention the distinguished name of Dr. Bostock, to consider it probable that all the anatomical varieties in the structure of the stomachs of different animals may be resolved into their *mechanical* effects upon the aliments submitted to their action; and that, whatever may be the chemical composition of the food, provided it be sufficiently comminuted or triturated, it will be equally acted upon by the gastric juice. We might here ask whether the nature of the digestive solvent itself may not at the same time vary with that of the food which excites its secretion, and whether in this way Nature, if not abruptly called upon, may not adapt her measures to her necessities?

Although it is not our intention to discuss, at any length, the question as to whether Nature originally intended that we should feed on animal or vegetable food, nor to follow the train of those speculative authors who have endeavoured to prove that animal food was not eaten before the deluge, but was introduced in consequence of the deterioration which the herbage sustained on that occasion,—there are, nevertheless, several points connected with the first of these questions which we consider as deserving some notice. Reasoning from the data afforded us by the researches of the comparative anatomist, we are undoubtedly authorised in pronouncing man to be an *omnivorous* animal, and this is perhaps the only generalisation of which the subject is susceptible; Broussonet, however, has ventured so far to refine upon this proposition as to decide upon his being more herbivorous than carnivorous in his nature; and, from the proportion which the different teeth bear to each other, he concludes that his mixed diet should consist of animal and vegetable food in the proportion of twenty to twelve. It is, however, quite clear that no rule of this kind can possibly be established. We have only to consider the different effects produced upon the body by these two species of food, to perceive that the circum-

stances of climate, season, exercise, habit, age, and individual peculiarity must at once oppose such an admission.

As every description of food is converted into blood, and since the flesh and blood of carnivorous and herbivorous animals do not differ very materially from each other, it may be inferred that the ultimate effect of all aliments must be virtually the same; and that the several species can only differ from each other in the quantity of nutriment they afford, in the comparative degree of stimulus they impart to the organs through which they pass, and in the proportion of vital energy they require for their assimilation. Now were the degree of excitement which attends the digestion of a meal commensurate with the labour imposed upon the organs which perform it, it is quite clear that less irritation and heat would attend the digestion of animal than of vegetable food; for in the one case the aliment already possesses a composition analogous to that of the recipient, and requires little more than division and depuration; whereas in the other a complicated series of decompositions and recompositions must be effected before the matter can be animalised, or assimilated to the body. But the *digestive fever*, (if we may be allowed to apply such an expression to a healthy process,) and the complexity of the alimentary changes, would appear in every case to bear an inverse relation to each other. This must depend upon the fact of animal food affording a more highly animalised chyle, or a greater proportion of that principle which is essentially nutritive, as well as upon the immediate stimulus which the nerves receive from its contact. In hot countries, therefore, during the heat of summer, we are, as it were, instinctively led to prefer vegetable food; and we accordingly find that the inhabitants of tropical climates select a diet of this description. The Brahmins in India, and the people of the Canary Islands, Brazils, &c., live almost entirely on herbage, grains, and roots, while those of the north use little beside animal food. On account of the superior nutritive power of animal matter, it is equally evident that the degree of bodily exertion, or exercise, sustained by an individual, must not be overlooked in an attempt to adjust the proportion in which animal and vegetable food should be mixed. Persons of sedentary habits are oppressed, and ultimately become diseased, from the excess of nutriment which a full animal diet will occasion; such a condition, by some process not well understood, is best corrected by acescent vegetables. It is well known that artisans and labourers, in the confined manufactories of large towns, suffer prodigiously in their health whenever a failure occurs in the crops of common fruits. This fact was remarkably striking in the years 1804 and 1805. Young children\* and growing youths generally thrive upon a generous diet of animal food; the excess of nutritive matter is consumed in the development of the body, and if properly digested imparts strength without repletion. Adult and old persons comparatively require but a small proportion of aliment, unless

the nutritive movement be accelerated by violent exercise and hard labour.

Those who advocate the exclusive value of animal food, and deny the utility of its admixture with vegetable matter, adduce in support of their system the rude health and Herculean strength of our hardy ancestors. The British aborigines, when first visited by the Romans, certainly do not appear to have been conversant with the cultivation of the ground, and according to the early writers, Cæsar, Strabo, Diodorus Siculus, and others, their principal subsistence was on flesh and milk; but before any valid conclusion can be deduced from this circumstance, the habits of the people must be compared with those of their descendants. The history of later times will furnish us with a satisfactory answer to those who deny the necessity of vegetable aliment. We learn from the London bills, that scurvy raged to such an excess in the seventeenth century as to have occasioned a very considerable mortality: at that period the art of gardening had not long been introduced. It appears that the most common articles of the kitchen-garden, such as cabbages, were not cultivated in England until the reign of Catharine of Arragon; indeed, we are told that this queen could not procure a salad until a gardener was sent for from the Netherlands to raise it. Since the change thus happily introduced into our diet, the ravages of scurvy have been less severely experienced.

It follows, then, that in our climate a diet of animal food cannot with safety be exclusively employed. It is too highly stimulant: the springs of life are urged on too fast; and disease is the necessary consequence. There may, nevertheless, exist certain states of the system which require such a stimulus, and there may also exist a condition of the digestive organs which renders them incapable of assimilating vegetable food; the physician, therefore, may occasionally confine his patient to an animal regimen with as much propriety as he would prescribe opium or any other powerful remedy. By a parity of reasoning, the exclusive use of vegetable food may be shown to be inconsistent with the acknowledged principles of dietetics, and to be incapable of conveying a nourishment sufficiently stimulating for the active exertions which belong to our present civilized condition. At the same time, it must be allowed that an adherence to a vegetable diet is usually productive of far less evil in sedentary habits than that which follows the use of an exclusively animal regimen.

A very curious chapter might be written upon the adverse opinions which the physicians of different ages have maintained as to the importance of dietetic observances for the preservation of health and the cure of disease. Hippocrates was the first who attempted to establish any general principles upon the subject of dietetics; but accurate as he was in all his observations of the phenomena of disease, and admirable as are his precepts for its management, so warped were his notions with regard to the nature of aliments, by an absurd and predominating theory, that, instead of gathering from the stores of his experience any useful information, we find nothing but a mass of the most extraordinary conceits. Assuming as

\* The aliment of almost every animal, in its first stage of life, is composed of animal matter; even the graminivorous birds are nourished by the yolk of the egg for several days after being hatched.

the directing principle of all his researches, that living bodies contain two elements, differing in power but agreeing in purpose, viz. *fire* and *water*, which, with their consequences, heat and dryness, moisture and cold, he considers as necessary and sufficient for the maintenance of all the functions, — the water nourishing and the fire setting in motion. — he proceeds, after showing that disease arises from the deficiency of one or the other of these elements, to enumerate the different articles of diet which, from their heating, drying, moistening, and cooling tendencies, are best calculated to counteract such morbid states. He tells us, for instance, that fowls of every kind are drier than quadrupeds, because they have no bladder, and neither secrete urine nor saliva; thereby showing that the heat of the body dries up its moisture. Their eggs, he says, are strong, nourishing, and inflating; strong, because they contain the germ of an animal, — nourishing, because they nurse it, as it were, with milk, — and inflating, because they become dilated from a tiny particle to a large size. But it was not to be expected that, anterior to the discovery of the circulation of the blood, or to the existence of chemistry as a science, any rational views could be entertained upon a subject so entirely dependent upon such knowledge for its explanation. There exists, however, a connection between a class of phenomena which the ancient physicians recognised, and which the moderns appear to have too hastily disclaimed, — we allude to what they termed *non-naturals*; so called from their not being essential to the mere nature or constitution of living animals, and which, besides the different aliments, included air, exercise, sleep, the excretions, and the passions of the mind. In the second part of this article, it will be the endeavour of the writer to point out and enforce upon the mind of the practitioner, the very important relations which obtain between the different stages of digestion and the non-naturals above enumerated.

In modern times, the multiplied resources of pharmacy, and the discovery of new chemical agents, have naturally enough led practitioners to depend upon such remedies for the cure of chronic disease rather than upon a modified plan of diet; while, in the circle of the profession, a certain degree of distrust, or we might even add of opprobrium, has fallen upon such practitioners as have insisted upon its paramount importance. This circumstance easily admits of explanation. In physic a remedy or a practice has never been discarded by the regular practitioner but it has immediately found a patron in the empiric, who seizes upon it with avidity, in order to convert it to his own advantage, just as the rabble dress themselves in the cast-off clothes of their superiors.

The minor writers who have swarmed within the last half century have greatly contributed to throw discredit upon the subject. Nothing cherishes the public scepticism, with regard to the efficacy of the medical art, so much as the publication of the adverse and contradictory opinions of its professors upon points so apparently simple and obvious, that every superficially informed person constitutes himself a judge of their merits. If a reader is informed by one class of authors

that a weak stomach is unable to convert *liquid* food into aliment, and by another that *solid* food is injurious to feeble stomachs, he at once infers that the question is one of perfect indifference; and ultimately arrives, by a very simple process of reasoning, at the sweeping conclusion that the stomach, ever kind and accommodating, indiscriminately converts every species of food into nourishment, and that he has therefore only to consult his own inclination in its selection. On the valetudinarian, incapable of healthy reflection, and ever seeking for causes of fear and anxiety when they do not choose to come uncalled, such works may have a contrary tendency, and lead him to suspect the seeds of disease in every dish, and poison in every cup.

It appears to us that authors have in general laid far too great stress upon the quality of the different species of food, and have condemned particular aliments for those effects which should be attributed to their quantity, and still more perhaps to the circumstances under which they were taken; their dietetic precepts have therefore frequently assumed the air of ascetic austerities, and they have thus represented the cure far more formidable than the disease. It has been sarcastically observed by a popular writer, more remarkable for the playfulness of his style than for the soundness of his logic, that there exists a more intimate connection between the doctrine of Tertullian and that of many a dietetic practitioner, than is generally supposed; that he is the ascetic intrenched in gallipots and blisters, preaching against beef and porter; terrifying his audience with fire and brimstone in one age, and in the other with gout and apoplexy. Now, while we must all deeply lament that the severity of this sarcasm should have been in some measure sanctioned by the theoretical absurdities of many of our writers, it is impossible that any reasonable person can seriously contend that numerous diseases do not arise from an improper management of diet; much less that a judicious regulation of it cannot be rendered subservient to their cure. To those, however, if such there be, who do question the importance of dietetics, we have only to observe that they may as well deny the utility of the medical art altogether, and assert that, in all disorders of function, Nature is sufficiently powerful to rectify and cure them, without the intervention of art. Unless this be granted, it is absurd to say that beneficial impressions may not be made as well through the medium of the *materia alimentaria* as through that of the *materia medica*; or, to borrow the language of Dr. Arbuthnot, that what we take daily by *pounds* must not be, at least, as important as what we take seldom, and only by grains or tea-spoonsful.

To get rid of such a difficulty, a class of philosophers admit the salutary influence of particular aliments in rectifying disorders of function, but deny the necessity of reason or philosophy for the selection or management of them, since they consider that Nature has implanted in us instincts sufficiently strong and intelligible to direct us, under all circumstances, to what is salutary, and to warn us from such food as may be injurious. We may observe in reply, that man has so long forsaken the simple laws which Na

ture had instituted for his direction, that it is to be feared she has abandoned her charge, and left him under the control of that faithless guide and usurper, to which civilization has given birth. Appetite, which expresses the true wants of the system, can no longer be distinguished from that feeling which induces us to prefer one species of food to another, and which is the offspring of habit, and the consequence of artificial associations. Nor must it be forgotten that, during disease, the senses frequently lose their tact, and the invalid experiences an appetite for things that would be prejudicial.

That the natural relations which subsist between the qualities of food and the impressions made by them on the senses, are changed or destroyed by the refinements of artificial life, is a fact supported by many powerful arguments. How many kinds of aliment, originally disagreeable, become pleasant by habit? and how many substances, naturally agreeable, become disgusting from the creation of certain prejudices? We are acquainted with a lady who is always made sick by eating a green oyster; the cause of which may be traced to an erroneous impression she received with respect to the nature of the colouring matter. Dr. Fordyce has urged a still more serious and conclusive objection to that hackneyed maxim, "that we ought to live *naturally*, and on such food as is presented to us by nature," viz., that *man has no natural food*. It is decreed that he shall earn his bread by the sweat of his brow; or, in other words, that he shall by his industry discover substances from which he is to procure subsistence; and that, if he cannot find such, he must cultivate and alter them from their natural state. There is scarcely a vegetable which we at present employ that can be found growing naturally. Buffon states that our wheat is a factitious production, raised to its present condition by the art of agriculture. Rice, rye, barley, or even oats, are not to be found wild, that is to say, growing naturally, in any part of the earth, but have been altered, by the industry of mankind, from plants not now resembling them in such a degree even as to enable us to recognise their relations. The acrid and disagreeable *apium graveolens* has been thus transformed into celery; and the *colewort*, a plant of scanty leaves, not weighing altogether half an ounce, has been improved into cabbage, whose leaves alone weigh many pounds; or into a cauliflower of considerable dimensions, being only the embryo of a few buds, which, in their natural state, would not have weighed many grains. The potato again, whose introduction has added so many millions to our population, derives its origin from a small and bitter root, which grows wild in Chili and at Monte Video. If any of our readers, in the face of such facts, still remain sceptical upon the subject of these metamorphoses, let them visit the fairy bowers of horticulture, and they will there perceive that her wand has not only converted the tough, coriaceous covering of the almond into the soft and melting flesh of the peach, but that, by her spells, the our slue has ripened into the delicious plum, and the austere crab of our woods into the golden pippin; that this again has been made to sport in almost endless variety, emulating in beauty of

form and colour, in exuberance of fertility, and in richness of flavour, the rarer productions of warmer regions and more propitious climates. If cultivation can ever be said to have left the transformation of vegetables imperfect, the genius of cookery is certainly entitled to the merit of having completed it; for whatever traces of natural qualities may have remained, they are undoubtedly obliterated during their passage through her potent alembic.

After all, then, experience can alone supply the want of instinct, and form the basis of a rational system of dietetics. Experience, dearly bought experience, has taught us that headach, flatulency, hypochondriasis, and a thousand nameless ills, have arisen from the too prevailing fashion of loading our tables with a host of *entremets* and *hors d'œuvres*, which have too frequently usurped the roast beef of old England. The theorist, in the true spirit of refinement, laughs at our terrors: he admits, to be sure, that the man who eats round the table, "ab ovo usque ad mala," is a terrific glutton, but that, after all, *he has only eaten words*; for, eat as he may, he can only eat animal matter, vegetable matter, and condiment, either cooked by the heat of water or by that of fire,—figure or disfigure, serve, arrange, flavour, or adorn them as you please. There is not a physician of any practical knowledge who cannot, at once, refute such a doctrine by a reference to facts; every old nurse knows from experience, that certain mixtures produce deleterious compounds in the stomach, although the chemist may, perhaps, fail in explaining their nature, or the theory of their formation. What would such a reasoner say, if he were invited to a repast, and were presented only with charcoal and water? Would he be reconciled to his fare by being told that his discontent was founded on a mere delusion,—that the difference between them and the richest vegetable viands was merely ideal,—an *affair of words*,—as, in either case, he would only swallow *oxygen, hydrogen, and carbon*? And yet we will venture to assert that the presumption in such a case would not be more violent, nor more opposed to the just principles of physiology and chemistry, than is the argument by which the sciolist attempts to defend a practice which converts our refreshments into burdens, and our food into poison.

#### I. MATERIA ALIMENTARIA.

Those bodies which have possessed life can alone be strictly considered as affording aliment to animals; and yet there exist a certain number of inorganic substances, such as water, common salt, lime, &c. which, although incapable by themselves of nourishing, appear, when administered in conjunction with the former, to contribute essentially to nutrition. The consideration, therefore, of the *materia alimentaria* necessarily embraces, not only the *substantive* agents above stated, but those accessories which from their *modus operandi* might properly enough be entitled *alimentary adjectives*. Under the former division will be arranged all the varieties of animal and vegetable food; under the latter, the class of *condiments* will merit our attention.

The arrangements which different authors have proposed for the classification of alimentary sub-

stances will be found to vary according to the particular theory by which each may have been influenced. The chemist investigates the composition of an aliment, and arranges it either according to the ultimate elements of which he supposes it to consist, or according to the proximate principles which he considers to predominate in its composition. The naturalist, on the other hand, merely inquires to what division in his zoological system each article of diet belongs, and assigns to it a corresponding place in his arrangement; while the experienced practitioner is disposed to distribute the *nutrientia* in an order which answers to his notions of their relative nutritive value, or to the supposed facility with which they are dissolved in the stomach: thus, for example, as he finds from experience that the darkest coloured flesh generally contains more nourishment, while it stimulates the system more powerfully than the whiter kinds, he distributes venison, beef, mutton, hare, &c. into one group, while lamb, veal, and the white meats, such as that of turkey, partridge, pheasant, chicken, &c. he considers as constituting a different class.

Chemists have been ever anxious to reduce all nutritious substances to some one or more proximate principles. Haller attempted to resolve them into one elementary jelly. Cullen was of opinion that the matter of nutrition is, in all cases, either oily or saccharine, or what seems to be a combination of both these principles. Fordyce reduced all nutritious matter to mucilage; but since he admits of a *farinaceous* mucilage, a *saccharine* mucilage, &c., Dr. Bostock very justly remarks that the inaccuracy with which he may be charged is but of a verbal description. Richerand attempted to show that the nutritive principle is in all cases either gummy, mucilaginous, or saccharine. Dumas is disposed to regard "mucus" as the *principe eminentment nutritif*," by which he probably means albumen, since he observes that it forms the basis of our organs. Dr. Prout, whose researches in organic chemistry claim our highest attention and respect, has stated that he considers that there exist three great natural classes or groups, which essentially constitute the groundwork of all organized beings, which he denominates the *saccharine*, the *oleaginous* and the *albuminous*.

[The classification of Dr. Prout has been taken by Dr. Pereira (*A Treatise on Food and Diet*, Amer. edit. by Dr. C. A. Lee, p. 38, New York, 1843) as the basis of his own, which includes twelve divisions:—the *aqueous*; *mucilaginous*, or *gummy*; *saccharine*, *amylaceous*, *ligneous*, *pectinaceous*, *acidulous*, *alcoholic*, *oily* or *fatty*, *proteinaceous*, *gelatinous* and *saline*. By the combination of these alimentary principles and simple aliments, our ordinary articles of food, or compound aliments, are formed.]

M. Magendie has distributed the *nutrientia* into nine classes, according to the predominance of one or more of those proximate principles, upon the presence of which modern science has assumed that the nutritive qualities of substances mainly depend.

The following is his arrangement:

I. **FIBRINOUS ALIMENTS.**—Comprehending the flesh and blood of various animals, especially

such as have arrived at puberty;—venison, beef, mutton, hare.

II. **ALBUMINOUS.**—Eggs, &c.

III. **GELATINOUS.**—The flesh of young animals; veal, chickens, calf's foot, certain fishes.

IV. **FATTY AND OILY.**—Animal fats, oils, butter, cocoa, &c.; ducks, pork, geese, cels, &c.

V. **CASEOUS.**—The different kinds of milk, cheese, &c.

VI. **FARINACEOUS.**—Wheat, barley, oats, rice, rye, potato, sago, arrow-root, &c.

VII. **MUCILAGINOUS.**—Carrots, turnips, asparagus, cabbage, &c.

VIII. **SACCHARINE.**—The different kinds of sugar, figs, dates, &c.; carrots.

IX. **ACIDULOUS.**—Oranges, apples, and other acescent fruits.

If there be any truth in our dietetic experience, and any natural affinity between the objects of our classification, the theory of their arrangement will be unimportant; for, however greatly the roads of our pursuit may vary, we must all ultimately arrive at the same end. The danger of relying upon chemistry alone as our guide arises from the uncertainty in which the elementary nature of matter is involved. There can be but little doubt that the supplies by which the bodily waste is recruited are solely derived from the food, for experiments of the most refined nature have shown that no part of the air we breathe is absorbed by the lungs [!]; but it is more than doubtful whether those substances which are considered as the ultimate, or even the proximate, principles of our frame, are supplied to them ready formed by the aliments; or in other words, whether the powers of life do not analyse the matter submitted to them, and by recombining its elements, with which we are probably as yet unacquainted, produce those compounds which the chemist has been induced to suppose have been merely transferred from the ingesta, in order to be incorporated with the living structure. This is not only a highly curious, but a very important question in dietetics. If the views of the chemist be true, we have only to ascertain what principles may be excessive or defective in any state of disease, and at once to adopt a diet that may restore the healthy balance: but plausible and encouraging as such a theory may appear, an appeal to experience will at once prove it to be a delusion. The emaciated invalid can no more be restored to his plump contour by oleaginous ingesta, than the rickety child can be cured of a *mollities ossium* by the administration of phosphate of lime. "Nature," says Dr. Prout, "will not permit the chemist to officiate as her journeyman, even in the most trifling degree; or in other words, he is as little able to remedy or supply, in a direct manner, what is amiss or wanting in organic action, as he is to remedy or supply an injured nerve or muscle; and the only way in which, for the most part, he can hope to influence her operations, is through the indirect agency of those circumstances which naturally possess the power of influencing them, and the management and control of which are, to a certain extent, within his power." (Gulstonian Lecture, 1831.) This admission, however, by no means invalidates the utility of chemical inquiries with regard to the

nature of the different articles of diet; for as long as the composition of our diet possesses the power of influencing the constitution of our bodies, it is essential that we should be acquainted with its most minute details.

Amongst the numerous chemico-physiological questions which have arisen in connexion with the subject of dietetics, the late speculations of M. Magendie are not the least curious. It has been asserted by this distinguished physiologist that the azote or nitrogen of all the different tissues of the animal body can only be supplied by our food, and, consequently, that no substance which does not contain this principle can support life. In order to acquire some more exact notions on this subject, he submitted several animals, during a necessary period, to the use of food of which the chemical composition was accurately ascertained. We shall present our readers with a short abstract of these experiments, and then explain the different, but not less important, conclusions which we are prepared to deduce from their results. He took a dog of three years old, fat, and in good health, and put it to feed upon sugar alone, and gave it distilled water to drink: no restrictions were imposed as to quantity. It appeared very well in this way of living for the first seven or eight days; it was brisk, active, ate eagerly, and drank in its usual manner. It began to get thin in the second week, although its appetite continued good, and it took about six or eight ounces of sugar in twenty-four hours. Its alvine excretions were neither frequent nor copious; that of urine was very abundant. In the third week its leanness increased, its strength diminished, the animal lost its liveliness, and its appetite declined. At this period there was developed, first upon one eye, and then on the other, a small ulceration on the centre of the transparent cornea; it increased very quickly, and in a few days was more than a line in diameter; its depth increased in the same proportion; the cornea was very soon entirely perforated, and the humours of the eye ran out. This singular phenomenon was accompanied with an abundant secretion of the glands of the eyelids. The dog, however, became weaker and weaker; and, though it ate from three to four ounces of sugar per day, it became so weak that it could neither chew nor swallow; for the same reason every other motion was impossible. It expired the thirty-second day of the experiment. M. Magendie opened the animal with every suitable precaution. He found a total want of fat; the muscles were reduced to less than five-sixths of their ordinary size; the stomach and intestines were also much diminished in volume, and strongly contracted. The gall and urinary bladders were distended by their proper fluids, which M. Chevreul was called upon to examine. That distinguished chemist found in them nearly all the characters which belong to the urine and bile of *herbivorous* animals; that is, that the urine, instead of being acid as it is in *carnivorous* animals, was sensibly alkaline, and did not present any trace of uric acid, nor of phosphate. The bile contained a considerable portion of *picromel*, a character considered as peculiar to the bile of the ox, and in general to that of *herbivorous* animals. The excrements were also

examined by M. Chevreul, and were found to contain very little azote, whereas they usually furnish a considerable quantity. M. Magendie considered that such results required to be verified by new experiments; he accordingly repeated them on other dogs, but always with the same conclusions. He therefore considered it proved, that sugar by itself is incapable of supporting dogs. This want of the nutritive quality, however, might possibly be peculiar to sugar; he therefore proceeded to inquire whether other substances, *non-azotised*, but generally considered as nutritive, would be attended with the same consequences. He fed two dogs with olive oil and distilled water, upon which they appeared to live well for about fifteen days; but they afterwards underwent the same series of accidents, and died on the thirty-sixth day of the experiment. In these cases, however, the ulceration of the cornea did not occur. Gum is another substance that is said not to contain azote, but which is considered as nutritive. To ascertain whether it acted like sugar and oil, several dogs were fed exclusively upon it, and the phenomena did not sensibly differ from those above described. An experiment was then instituted with butter, an animal substance which, like the preceding, is considered as not possessing any azote in its composition. The dog was supported by it very well at first; but in about fifteen days it began to lose flesh and to become weak: it died on the thirty-sixth day, although on the thirty-fourth he gave it as much flesh as it would eat, a considerable quantity of which it took for two days. The right eye of this animal presented the ulcerations of the cornea. The opening of the body exhibited the same modifications of the bile and urine.

In order to make the evidence furnished by the above experiments as complete as possible, after having given to dogs separately, oil, sugar, or gum, he opened them, and ascertained that these substances were each reduced to a particular chyme in the stomach, and that they afterwards furnished an abundant chyle; whence he argues that, if these different substances are not nourishing, it cannot be attributed to the want of digestion.

We are anxious to give all due credit to the accuracy with which these experiments were performed, but we deny the conclusions which this eminent physiologist has deduced from their results. We meet him at once, by questioning the truth of his very first proposition, that sugar, oil, and gum cannot furnish azote. Is there a chemist of the present day who does not believe, although he is unable to prove it by direct experiment, that azote is a compound? The sugar therefore may furnish its elements, although we cannot detect azote during its decomposition in our laboratories. But let us waive this objection; we are quite prepared to impugn his conclusion on other grounds. What do his experiments prove? In the first place, the fact which we have before stated,—that an animal cannot bear a sudden and permanent change in its diet without injury; and in the next place, that a highly concentrated diet, or food which does not contain an intermixture of innutritive parts, is always injurious.

M. Magendie has himself, by subsequent ex-

periments, furnished evidence against his own theory; for a dog confined on a diet of white bread, the gluten of which contains an abundance of azote, perished like those fed on sugar or gum. Animals, moreover, which were kept upon cheese, and even upon hard boiled eggs, became diseased, and yet *casein* is a highly azotised principle, while albumen is considered by Berzelius as the peculiar source of all the animal secretions.\*

[That the effects were not owing to the privation of azote, Magendie has of late been still more amply satisfied. (*Comptes Rendus*, Août, 1841.) In the name of a committee appointed to inquire into the nutritive properties of gelatin, he reported, as chairman, that gelatin, albumen, and fibrin—all of which are highly azoted—when taken separately, nourish animals for a very limited period only, and in an imperfect manner. They generally soon excite such insurmountable disgust, that the animals die rather than partake of them. These experiments have led to the too hasty conclusion, that the gelatinous tissues are incapable of conversion into blood. "The gelatinous substance," says Liebig, (*Animal Chemistry*, Amer. edit. by Webster, p. 124, Cambridge 1842,) "is not a compound of protein: it contains no sulphur, no phosphorus, and it contains more nitrogen or less carbon than protein. The compounds of protein, under the influence of the vital energy of the organs which form the blood, assume a new form, but are not altered in composition; whilst these organs, as far as our experience reaches, do not possess the power of producing compounds of protein, by virtue of any influence, out of substances which contain no protein. Animals, which were fed exclusively on gelatin, the most highly nitrogenized element of the food of carnivora, died with the symptoms of starvation." "In short," he adds, "the gelatinous tissues are incapable of conversion into blood." Yet, it has been shown above, that fibrin and albumen—both compounds of protein—when exhibited alone to animals, nourished them as imperfectly as gelatin.

The experiments of Magendie show the necessity for variety of food for prolonged animal health and existence. Much, doubtless, depends on the habits of the particular animal or individual, and on the morbid effects excited by completely modifying the function of assimilation, as it has been ordinarily practised. It has been long known, that if a person, previously habituated to both animal and vegetable diet, be restricted to one or other exclusively, he will fall off, and become scorbutic; and yet he is capable of subsisting upon either, provided he be restricted to it from early infancy.

Of late, great light has been thrown on this subject by the researches of the organic chemist. These have shown, that the chief proximate principles of animal tissues, and those that have been regarded as highly nutritious amongst vegetables, have almost identically the same composition. (Liebig, *op. cit.*, p. 100.) They all contain nitrogen, or are "nitrogenized." The following tables

from Liebig exhibit this similarity of constitution in a striking manner:—

*Animal Proximate Principles, according to Mulder.*

	Albumen.	Fibrin.	Casein.
Carbon, . . . . .	54.84 . . . .	54.56 . . . .	54.96 . . . .
Hydrogen, . . . . .	7.09 . . . .	6.90 . . . .	7.15 . . . .
Nitrogen, . . . . .	15.83 . . . .	15.72 . . . .	15.80 . . . .
Oxygen, . . . . .	21.23 . . . .	22.13 . . . .	21.73 . . . .
Sulphur, . . . . .	0.68 . . . .	0.33 . . . .	0.36 . . . .
Phosphorus, . . . .	0.33 . . . .	0.36 . . . .	
	100.00	100.00	100.00

*Vegetable Proximate Principles, according to Scherer and Jones.*

Phosphorus, . . . .			
	100.00	100.000	100.000

It has been maintained by Liebig and by others, that nitrogenized or azoted aliments are alone capable of forming organized tissues. These, consequently, have been classed by Liebig as *plastic elements of nutrition*; whilst non-nitrogenized aliments being, in his opinion, inservient only to respiration, are termed by him *elements of respiration*. All this, however, requires proof, and is combated by what we observe in chylickification. In the small chylickiferous vessels, more fat, which is non-nitrogenized, is contained than can be accounted for by the fat in the food; and as the chyle proceeds, the proportion of fat becomes less and less, whilst that of the nitrogenized elements increases; hence, nitrogen must be obtained, and a conversion, doubtless, takes place of non-nitrogenized into nitrogenized elements.]

We have said that a certain volume or bulk seems to be a necessary condition of wholesome food;—does not the capacity of the digestive organs sufficiently show that Nature never intended them for the reception of highly-concentrated food? This truth is still further exemplified by the very sparing manner in which she produces concentrated aliment; the saccharine matter of esculent fruits is generally blended with acidulous and mucilaginous ingredients, and the oleaginous matter is thus combined with the farinaceous, in seeds, kernels, and other substances of this description. The evils arising from the use of a too concentrated diet are well known to the physician; and, if we extend our observations to the domestic animals under our care, we shall derive further evidence of this important fact. A great number of our horses are fed with oats and beans, the nutriment of which is condensed into a much smaller space than it could generally be in natural provender; and these animals, when supported on such food, are consequently liable to various ailments originating from diseased action in the stomach, or from general plethora; in short, it need scarcely be remarked that horses so fed, and unnaturally confined in stables, require to be bled and purged to preserve their lives. The animal,

\* The ingenious experiments of Mr. Hatchett also show that albumen is the *parent* fluid from which other principles may be formed; he found, for instance, that it was convertible into gelatine and fibrine.—*Phil. Trans.* 1800.

thus abused evidently suffers from acidity, as we find him frequently eating absorbent earths with avidity.\* The extraordinary exertions often required of horses render it necessary that they should be better fed than when existing in a more natural state; and since they do not travel so well with a full stomach, it is also necessary to adopt the use of food in which the nutriment is reduced into the smallest compass. Post-horses and others, whose motion must be rapid, are therefore chiefly fed with corn alone; but what is the effect?—fermentation instead of digestion; as the intolerable odour which assails us in the stable, under such circumstances, and the decomposed glass of its windows from the sulphuretted hydrogen acting upon the lead contained in it, sufficiently testify. Did it never occur to the physiologist, that had Nature intended animals to feed only upon the concentrated aliment of gramineous and leguminous vegetables, she would have supplied them with an apparatus by which they might separate the chaff and straw from the grain?

These remarks may be applied to man: we shall have occasion to show hereafter that the use of chocolate, butter, cream, sugar, and rich sauces, without a due admixture of bread, potatoes, and other less concentrated aliment, is invariably attended with disordered digestion. Unless the taste be vitiated, there exists an instinctive aversion to such food—

“the prudent taste  
Rejects, like bane, such loathsome lusciousness.”

The Kamtschatdales are frequently compelled to live on fish-oil, but they judiciously form it into a paste with saw-dust, or the rasped fibres of indigenous plants.

**Nutritiveness and Digestibility of different kinds of Food.**—Before we attempt to appreciate the value of the different articles of the materia alimentaria, it will be necessary to caution the reader against the popular error of regarding the terms digestible and nutritive as synonymous and convertible. A substance may be highly nutritive and yet be digested with difficulty; that is to say, it may require all the powers of the digestive organs to convert it into chyle, and yet, when so converted, it may afford a principle of highly restorative energy: this is the case with the fatty and oily elements.† On the contrary, there are substances which apparently pass out of the stomach with sufficient readiness, but afford but little comparative support to the body.

Writers on dietetics have descanted very learnedly upon what they please to term the *perspirability* and *alkalescency* of certain aliments. To the former we are quite unable to attach any precise meaning; with respect to the latter, we apprehend that it is intended to express a highly nutritive quality, with a certain degree of indigestibility. *Heavy* and *light*, as applied to food, are terms equally vague and indefinite, and ought never to be introduced into writings which aspire to the character of philosophical precision. The observation may be extended to the epithet *bilious*.

It is only necessary to reflect upon the chemical and mechanical processes by which chymi-

fication is performed in the stomach, to perceive that the digestibility of a substance may depend upon other circumstances than that of its chemical composition. Its mechanical state with regard to texture and consistence, is of the highest importance; and if we attempt to deduce any law upon this subject, from the known solubility of a substance out of the body, we shall fall into several fatal errors. It will be necessary to investigate this question with some attention, for it not only explains the relative digestibility of aliments, but furnishes the only true basis for a system of skillful cookery.

The healthy stomach disposes most readily and effectually of solid food, of a certain specific degree of density, which may be termed its *digestive texture*; if it exceed this, it will require a greater length of time and more active powers to complete its chymification; and if it approaches too nearly to a gelatinous condition, the stomach will be equally impeded in its operations. It is, perhaps, not possible to appreciate or express the exact degree of firmness which will confer the highest order of digestibility upon food;‡ indeed this point may vary in different individuals; but we are taught by experience that no meat is so digestible as tender mutton: when well-conditioned, its fibre appears to possess that degree of consistence which is most congenial to the stomach; and in this country it is perhaps more universally used than any other animal food. Wedder mutton, or the flesh of the castrated animal, is in perfection at five years, and is by far the sweetest and most digestible. Ewe mutton is best at two years old. Beef appears to be not so easy of digestion; its texture is firmer, but it is equally nutritive; much, however, will depend upon the period which has elapsed since the death of the animal, and more upon the method of cookery; in short, it would be worse than useless to attempt the construction of any scale to represent the nutritive and digestive qualities of the different species of food: the observations here introduced are merely noticed for the sake of illustrating those general principles whose application can alone afford us any rational theory of diet.

It will not be difficult to understand why a certain texture and coherence of the aliment should confer upon it digestibility or otherwise. Its conversion into chyme is effected by the solvent power of the gastric juice, aided by the *churning* which it undergoes by the motions of the stomach; and unless the substance introduced possesses a suitable degree of firmness, it will not yield to such motions: this is the case with soups and other liquid aliments; in such cases, therefore, nature removes the watery part before digestion can be carried forward. It is on this account that oils are digested with so much difficulty; and it is probable that jellies and other glutinous matters, although containing the elements of nourishment in the highest state of concentration, are not digested without considerable difficulty; in the first place, on account of their evading the grappling powers of the stomach, and, in the next, in

\* The habit of crib-biting may perhaps be attributed to such a source.

† It has been calculated that an ounce of fat meat affords nutriment equal to four ounces of lean.

‡ Some experiments were introduced for this purpose by Gosse, of Geneva; but the conclusions deduced from them are by no means satisfactory. He confounds solubility with digestibility, which in itself is sufficient to vitiate his reasoning.

consequence of their tenacity opposing the absorption of their more fluid parts. For these reasons the addition of isinglass and other glutinous matter to animal broths, with a view to render them more nutritive to invalids, is a questionable custom.

The texture of animal food is greatly influenced by the age, sex, habits, condition, diet, and description of death of the animal which furnishes it. In proportion generally to the age, its flesh is coarser and more firm in texture, as every one must have noticed in eating birds. If the flesh of mutton and lamb, beef and veal, are compared, they will be found of a different texture; the two young meats are of a more stringy, indivisible nature than the others, which makes them harder of digestion. It has been also justly observed that young animals differ from old ones in the distribution of the fat, which in the latter is chiefly collected in masses or layers, external to the muscles; whereas in the former it is more interspersed among the muscular fibres, giving the flesh a marbled appearance, which is always a desirable property of butchers' meat. The texture of food will also vary according to the wild or domesticated state of the animal; that of the former is more dense, although highly nutritive. The sex also modifies the quality of the flesh, that of the female being always more delicate and finer-grained than that of the entire male, whose fibres are denser. The influence of the genital organs upon this occasion is very extraordinary; it is generally believed that the flavour of the female is even improved by removing the ovaries, or *spaying* them, as it is called. Every day the testes are permitted to remain, even though totally inactive with regard to their proper functions, injures the delicacy of the veal of the bull calf; and an animal which is not castrated until after puberty always retains much of the coarseness of the entire male. The mode of killing an animal has been considered, from the remotest ages, as capable of affecting the quality of its meat. The flesh of hunted animals is characterized by peculiar tenderness: the same effect is produced by any lingering death. This fact probably explains the policy of those old municipal laws which ordained that no butcher should offer or expose any bull-beef for sale unless it had previously been bled; and it is upon the same principle only that the quality of pig's flesh could be improved by the horrid cruelty of whipping them to death, as said to be practised by the Germans. The action of vinegar, administered to an animal some hours before killing it, is also known to be capable of rendering its flesh less tough. It is a common practice in the country to give a spoonful of this acid to poultry, when they are intended for the immediate service of the table.

Nothing, however, tends more effectually to ameliorate the rigidity of the animal fibre than incipient putrefaction. The length of time that meat ought to be kept after it is killed will necessarily depend upon its tendency to undergo the putrid fermentation, and the prevalence of those circumstances which are inclined to favour it.

The circumstances which have been just enumerated, as being capable of influencing the texture of our food, and consequently its degree of digestibility, are, however, unimportant when com-

pared with the modifying powers of cookery, which we shall now proceed to examine.

**Cookery.**—By cookery, alimentary substances undergo a two-fold change; their principles are *chemically* modified, and their textures *mechanically* changed. The extent and nature, however, of these changes will greatly depend upon the manner in which heat has been applied to them; and if we inquire into the culinary history of different countries, we shall trace its connection with the fuel most accessible to them. This fact readily explains the prevalence of the peculiar species of cookery which distinguishes the French table, and which has no reference, as some have imagined, to the dietetic theory or superior refinement of the inhabitants.

By the operation of *boiling*, the principles not properly soluble are rendered softer, more pulpy, and, consequently, easier of digestion; but the meat, at the same time, is deprived of some of its nutritive properties by the removal of a portion of its soluble constituents: the albumen and gelatin are also acted upon; the former being solidified, and the latter converted into a gelatinous substance. If, therefore, our meat be boiled too long or too fast, we shall obtain, where the albumen predominates, as in beef, a hard and indigestible mass, like an over-boiled egg; or where the gelatin predominates, as in young meats, such as veal, a gelatinous substance equally injurious to the digestive organs. Young and viscid food, therefore, as veal, chickens, &c., is more wholesome when roasted than when boiled, and is easier digested. Dr. Prout has very justly remarked that the boiling temperature is too high for a great many of the processes of cooking, and that a lower temperature and a greater time, or a *species of infusion*, are better adapted for most of them. This is notorious with substances intended to be *stewed*, which, even in cookery-books, are directed to be *boiled slowly*, (that is, not at all,) and for a considerable time.\* The ignorance and prejudice existing on these points is very great, and combated with difficulty; yet, when we take into account their importance, and how intimately they are connected with health, they will be found to deserve no small share of our attention. The loss occasioned by boiling partly depends upon the melting of the fat, but chiefly from the solution of the gelatin and osmazone; mutton generally loses about one-fifth, and beef about one-fourth, of its original weight. Boiling is particularly applicable to vegetables, rendering them more soluble in the stomach, and depriving them of a considerable quantity of *air*, so injurious to weak stomachs. But even in this case, the operation may be carried to an injurious extent; thus potatoes are frequently boiled to the state of a dry insipid powder, instead of being preserved in that state in which the parts of which they are composed are rendered soft and gelatinous, so as to retain their shape, and yet be very easily separated. On the other hand, the cabbage tribe and carrots are frequently not boiled long enough, in which state they are highly indigestible. In conducting this process it is necessary to pay some attention

\* Hence it is that beef-tea and mutton-tea are much more calculated for invalids than the broths of these meats.

to the quality of the water employed; thus, mutton boiled in hard water is more tender and juicy than when soft water is used; while vegetables, on the contrary, are rendered harder and less digestible when boiled in hard water.

By the process of *roasting*, the fibrine is corrupted, the albumen coagulated, the fat liquefied, and the water evaporated. As the operation proceeds, the surface becomes first brown, and then scorched, and the tendinous parts are rendered softer and gluey. Care should always be taken that the meat should not be *over-done*, nor ought it to be *under-dressed*; for although in this latter state it may contain more nutriment, yet it will be less digestible, on account of the density of its texture. This fact has been satisfactorily proved by the experiments of Spallanzani; (Spallanzani on Digestion, vol. i. p. 277;) and Mr. Hunter observes that "*boiled, and roasted, and even putrid meat, is easier of digestion than that which is raw.*" (Hunter on the Animal Economy, p. 220.) Animal matter loses more by roasting than by boiling; it has been stated above, that by this latter process mutton loses one-fifth, and beef one-fourth; but by roasting, these meats lose about one-third of their weight. In roasting, the loss arises from the melting out of the fat, and the evaporation of the water; but the nutritious matter remains condensed in the cooked solid; whereas, in boiling, the gelatine is partly abstracted. Roasted are, therefore, more nutritive than boiled meats.\*

The process of *frying* is, perhaps, the most objectionable of all the culinary operations. The heat is applied through the medium of boiling oil, or fat, which is thus rendered empyreumatic, and therefore extremely liable to disagree with the stomach.

By *broiling*, the sudden browning or hardening of the surface prevents the evaporation of the juices of the meat, which imparts a peculiar tenderness to it. It is the form selected, as the most eligible, by those who seek to invigorate themselves by the art of *training*.

The peculiarity of the process of *baking* depends upon the substance being heated in a confined space, which does not permit the escape of the fumes arising from it; the meat is therefore, from the retention of its juices, rendered more sapid and tender. But baked meats are not so easily digested, on account of the greater retention of their oils, which are, moreover, in an empyreumatic state. Such dishes accordingly require the stimulus of various condiments to increase the digesting powers of the stomach.

[SOLID] ARTICLES OF DIET.—Were we to follow the steps of preceding writers on dietetics, we should present a catalogue of the nutriment, and introduce under each article a history of its composition and qualities; but the utility of general principles is to abbreviate labour, and to class under distinct heads those remarks which were previously scattered and unconnected.

We have seen that the nutritive qualities of a substance depend upon its composition; but that its digestibility may be influenced by various me-

chanical causes. It is by such tests that we have now to examine the several classes of food, and to assign to the individual bodies which they embrace their relative value as articles of diet.

**Milk** is the only nutritive fluid with which nature has presented us; but if we examine its chemical composition, we shall soon discover that it possesses an ingredient which is instantly coagulated in the stomach: so that, in fact, it must be regarded as a mixture of solid and liquid aliment; the latter, however, considerably exceeding the former in quantity, and thereby demonstrating the necessity of a greater portion of fluid than of solid matter, on which the necessity of alimentary supplies is founded.

Although recent milk appears as a homogeneous liquid, it may be resolved, partly by standing, and partly by agents that do not essentially alter the nature of its components, into three proximate ingredients, the *cream*, *curd*, and *whey*.

1. The **cream** rises to the surface of the milk, after it has stood for some hours, and may be skimmed off, and thus separated from it. It appears to possess many of the properties of oil, is smooth and unctuous to the touch, and stains cloth in the same manner as other unctuous substances. By standing for some days it becomes gradually thicker, and at length forms a soft solid, in which the flavour of cream is no longer perceived, and that of cheese is substituted in its place. According to the experiments of Berzelius, cream is a compound body, consisting of butter, 4.5; cheese, 3.5; and whey, 92 parts; but since the whey holds certain salts in solution, we may consider the whole of the solid matter contained in cream as amounting to 12.5 per cent. When cream is agitated, as is done by the common process of churning, it is separated into two parts; a thick animal oil, well known by the name of butter, and a fluid which possesses exactly the same properties as milk that has been deprived of its cream. This change has been supposed to be owing to the combination of the cream with the oxygen of the atmosphere; but it takes place, though perhaps not equally well, in vessels from which the air has been excluded.

2. When milk, either deprived or not of its cream, is mixed with certain substances, or allowed to stand till it becomes sour, it undergoes a change which is called coagulation, consisting of its separation into a solid substance termed **curd**, and a fluid called **whey**. This change may be effected by several agents, such as alcohol, gelatine, and all astringent vegetables; by acids and many neutral salts; by gum, sugar, and more particularly by the *gastric juice*. The effect is supposed to arise from the affinity of the coagulating substance for water, the curd, being principally albumen, having very little affinity for the same; but this theory can hardly explain the operation of the gastric juice: the infusion of a piece of calf's stomach, not larger than a half crown, will coagulate a quantity of milk sufficient for making a cheese of sixty pounds weight, although the quantity of coagulating matter cannot in this case exceed a few grains.

3. **Whey**, or the liquid which remains after the separation of the curd, is a thin and almost transparent fluid, of a yellowish-green colour, and

\* It has been computed that, from the dissipation of the nutritive juices by boiling, one pound of *roasted* contains as much nourishment as two of boiled meat.

a pleasant sweetish taste. It still contains, generally, a portion both of curd and of butter; the former of which may be separated by a boiling heat, in the form of coagulum. The buttery matter also separates by heat, especially if the whey be previously allowed to become sour. Whey contains, indeed, in its recent state, some acetic acid. When whey, which has been deprived as much as possible of the butter and curd, is slowly evaporated, it yields the peculiar substance termed "*sugar of milk*," which may be obtained, by clarification with the whites of eggs, in the form of crystals. The presence of the saccharine matter held in solution in whey enables that fluid to undergo the vinous fermentation; and it is accordingly employed by the Tartars for making a sort of wine, which is called *Koumiss*. For this purpose mare's milk is selected, as containing a larger portion of sugar than that of the cow. Whey also contains several saline bodies, viz., *muriate of potass*, *phosphates of lime and of iron*, and *sulphate of potass*; and a peculiar *animal matter*, which gives a precipitate with infusion of galls, and affords carbonate of ammonia by distillation.

Although nature has presented us with this compound fluid for the purposes of nourishment, and although it is evident that its several ingredients are wholesome, and designed for the various objects of aliment, yet, when separated by art, they are frequently unwelcome to the stomach; that viscus would appear to dislike the interference of the cook, in the performance of an analysis which its own powers are so well calculated to effect. We are well assured that the first process which takes place in the stomach for the chymification of milk, is its separation into curd and whey; and yet the former of these substances, when obtained by art, frequently proves highly oppressive to the stomach, and sometimes occasions obstructions in the bowels. **Cheese**, again, which is nothing more than the coagulum of milk, pressed, salted, and partly dried, with a portion of butter, which, having been enveloped in the curd, is not afterwards separable, is one of the least digestible of our aliments, and is only adapted to strong stomachs, and to such persons as use great and constant exercise. When *toasted*, it is still more injurious, from acquiring a tenacity of texture highly hostile to the digestive functions of the stomach. **Butter**, from its oily nature, is apt to disagree with delicate stomachs, and when rendered empyreumatic by heat, produces heartburn and other distressing symptoms. Whey differs considerably in its dietetic value, according to the method employed for its separation. When this is effected by *rennet*, it always holds a portion of cream and curd suspended in it, besides its quantity of sugar. It is, therefore, considerably nutritive; but it is, at the same time, more acedescant than milk, and hence it is liable to produce flatulence in those whose stomachs are disposed to encourage fermentation. Whey that has been produced by spontaneous coagulation always contains less nutritive matter, is more acid, and consequently more objectionable, unless, perhaps, as a drink in certain states of fever.

From this account of the composition of milk, several properties of the entire fluid may be under-

stood. By boiling it, its albuminous part is not coagulated into a mass like the white of an egg, on account of the large quantity of water through which it is diffused; but a thin pellicle forms on the surface, which, if removed, is immediately replaced by another; and thus the whole of the albumen may be separated in successive portions. The effect of this process is therefore to diminish the nutritive quality of the milk; but it may at the same time render it more easily digestible. We have known many invalids who could take boiled milk, but were unable to bear that fluid in its natural state.

Milk, in its dietetic relations, may be considered as intermediate between animal and vegetable food; it is easily assimilated, and therefore affords a quick supply of aliment to the system, while it does not excite that degree of vascular action which is produced by other animal matters. Its nutritive powers may be increased by various additions, which have also, on some occasions, the effect of correcting its natural tendency to acidity, and on others, that of obviating the costiveness which it is liable to occasion; such objects are sometimes fulfilled by adding oatmeal gruel to it. In certain states of organic disease, we have found that milk, impregnated with the fatty matter of mutton-suet, is a valuable article of diet: such a repast is best prepared by inserting the suet in a muslin bag, and then simmering it with the milk.

Before quitting this subject, it is necessary to observe that there exists some difference in the composition of the milk of different animals. That of the human subject is much thinner than cow's milk; is of a bluer colour, and contains much more saccharine matter. It also yields a larger proportion of cream, but from which the butter cannot be separated by agitation. It deposits a part of its curd by mere repose. Asses' milk bears a stronger resemblance to human milk than to any other; it contains more sugar than that of the cow, and the proportion of curd is so considerable as even to separate on standing, before the milk becomes sour. Goat's milk yields a remarkably thick and unctuous cream, and abounds also in curd.

**Eggs**, in point of nutriment and digestibility, may be classed next to milk; but their qualities will greatly depend upon the manner in which they have been cooked. When raw, they are certainly not so easily digested as when lightly boiled, so as slightly to coagulate their albuminous principle: but if this process be carried too far, they are converted into a hard mass, which requires a long period for their digestion: but this is much accelerated by the use of vinegar as a condiment. They are distinguished by the peculiar quality of singularly affecting some stomachs, even in the smallest quantity; while they do not produce any uneasy impressions on others. We are acquainted with a person who constantly finds an egg to produce uneasiness when his stomach is in the least deranged, but who can eat them with impunity at all other times. It is a notorious fact that eggs, when raw, are laxative, and when cooked are apt to produce costiveness.

**Fish** has been generally considered as holding a middle rank between the flesh of warm-blooded animals and vegetable food. It is certainly less

nutritive than mutton or beef; but the health and vigour of the inhabitants of fishing-towns evidently prove that it is sufficiently nourishing for all the purposes of active life: but in order to satisfy the appetite, a large quantity is requisite; and the appetite returns at shorter intervals than those which occur during a diet of meat. Nor does this species of food produce the same stimulus to the body; the pulse is not strengthened as after a repast of flesh; and that febrile excitement which attends the digestion of the more nutritive viands is not experienced. Hence fish affords a most valuable article of diet to invalids labouring under particular disorders; for it furnishes a chyle moderately nutritive, but at the same time, not highly stimulant. From the nature of its texture, it does not require a laborious operation of the stomach; although it is sufficiently solid to rescue it from those objections which have been urged against liquid or gelatinous food. From the observations just offered upon the nutritive powers of fish, it must follow that such a diet is not calculated to restore power to habits debilitated by disease, and should never be directed under such circumstances, but from the conviction that the digestive powers are unable to convert stronger aliment into chyle. The jockeys who *waste themselves* at Newmarket in order to reduce their weight, are never allowed meat when fish can be obtained. On account of the low stimulant power of fish, it requires the assistance of condiment; and on this account salt appears to be an essential accompaniment.

Fish have been arranged under three divisions, viz., *fresh-water fish, salt-water fish, and shell-fish*; but, since the value of these animals as articles of food has an intimate relation to the colour and texture of their muscles, and to their gelatinous or oily qualities, it will be expedient to consider their several varieties with reference to such conditions. Turbot, cod, whiting, haddock, flounder, and sole, are the least heating of the more nutritive species; and the flakiness of the fish, and its opaque appearance after being cooked, may be considered as true indications of its goodness; for when the muscles remain semi-transparent and bluish, after sufficient boiling, we may reject it as inferior in value, or not in season. When the fish is in high perfection, there is also a layer of white curdy matter, resembling coagulated albumen, interposed between its flakes. The whiting is well adapted to weak stomachs, on account of the little viscosity which it possesses; it is, at the same time, tender, white, and delicate, and conveys sufficient nutriment with but little stimulus to the system. The haddock much resembles it, but is firmer in texture. Cod has a more dense fibre than the two former, and contains also more glutinous matter: it is an excellent aliment, but upon the whole is not quite so digestible as whiting or haddock. It is generally preferred when large; but such fish are frequently coarse. The haddock is certainly better when it does not exceed a middling size. Turbot is an excellent article of food; but it is usually rendered difficult of digestion by the quantity of lobster sauce with which it is eaten. Sole is tender, and yet sufficiently firm; it is therefore easy of digestion, and affords proper nutriment to delicate stomachs. It is necessary to state that every part

of the same fish is not equally digestible; and it unfortunately happens that those which are considered the most delicate are, at the same time, the most exceptionable: the pulpy, gelatinous skin of the turbot, and the glutinous parts about the head of the cod, are very apt to disagree with invalids. Salmon may, perhaps, be considered the most nutritive of our fish; but it is heating and oily, and not very digestible: and persons, even with strong stomachs, are frequently under the necessity of taking some stimulant to assist its digestion. The addition of lobster sauce renders it still more unwholesome: the best condiment that can be used is vinegar. As connected with the time of spawning, the season of the year has the most decided influence upon the quality of salmon. It is in the highest perfection, or *in season*, as it is termed, some time previous to its spawning; the flesh is then firm and delicious; whereas, after this event, it is for some time unfit for food. Salmon trout is not so rich and oily as the salmon; although, therefore, it is less nutritive, it is at the same time less heating and more digestible. Eels are extremely objectionable, on account of the large proportion of oil which they contain. From these observations, the value of fish may be appreciated, and the qualities which entitle them to election easily understood. Firmness of texture, whiteness of muscle, and the absence of oiliness and viscosity are the circumstances which render them acceptable to weak stomachs.

*Shell-fish* have been greatly extolled by some physicians as nutritive and easily digestible articles of food. It will be necessary to examine this question by the application of those principles which we have endeavoured to establish. Oysters would appear to enjoy a reputation which they do not deserve; when eaten cold they are frequently distressing to weak stomachs, and require the aid of pepper as a stimulant; and since they are usually swallowed without mastication, the stomach has an additional labour to perform, in order to reduce them into chyme. When cooked they are still less digestible, on account of the change produced upon their albuminous principle. It is, however, certain that they are nourishing, and contain a considerable quantity of nutritive matter in a small compass. It is equally clear that oysters have occasionally produced injurious effects, (Medical Transactions of the College of Physicians, vol. v.); these have been attributed to their having lain on coppery beds, but this idea is entirely unfounded, and arose merely from the green colour which they often acquire, the cause of which is now generally understood, being sometimes an operation of nature, but more generally produced by art, by placing them in a situation where there is a great deposit from the sea, consisting of the vegetable germs of marine *conferve* and *fuci*, and which impart their colour to the oyster. For this object the Dutch formerly carried oysters from our coasts, and deposited them on their own. Native oysters, transported into the Colchester beds, soon assume a green colour. Where this food has produced a fit of indigestion, it has evidently arisen from the indigestible nature of the oyster, and the state of the individual's stomach at the time; and had such a person in-

indulged to the same amount in any equally indigestible aliment, there can be no doubt but that he would have experienced similar effects. Oysters cast their spawn, which the dredgers call the *spat*, in the month of May, after which they are sick and unfit for food; but in June and July they begin to mend, and in August they are perfectly well. We therefore see the cause of their going out of season, and discover the origin of the old maxim, that an oyster is never good except when there is an *r* in the month. Lobsters are certainly nutritive; but they are exposed to the same objection on the ground of indigestibility; and such has been their effect upon certain stomachs, as to have excited a suspicion of their containing some poisonous principle: they have been known to occasion pain in the throat, and, besides eruptions upon the skin, to extend their morbid influence to the production of pain in the stomach, and affection of the joints. As found in the London market, they are generally underboiled, with a view to their better keeping; and in that case they are highly indigestible. The same observations apply to the crab. Shrimps are a species of sea crab, which vary in their colour and size, and are considered easier of digestion than the preceding articles. The mussel is a species of bivalve which is more solid, and quite as indigestible as any animal of the same tribe. The common people consider them as poisonous, and, in eating them, take out a part in which they suppose the poison principally to reside. This is a dark part, which is the heart, and is quite innocuous: the fact, however, is sufficient to prove that this species of bivalve has been known to kill; but probably not more frequently than any other indigestible substance. Our annals abound with instances of the deleterious properties of melon, cucumbers, &c. and yet no one will contend that any poison, properly so called, resides in such vegetables. The peculiar cutaneous efflorescence which is produced by the imperfect digestion of shell-fish, has been observed to occur more frequently in cases where the fish has been stale or tainted, although it also happens where no such error can be suspected.

It has been usual to attribute all the cutaneous affections which follow the liberal use of fish as depending upon the sympathy of the skin with the stomach. This, we believe, is in general the true explanation, since the effect is merely temporary; and when the process of digestion is finished, it departs. Its departure may even be hastened by the operation of an emetic removing the noxious aliment. At the same time the fact must not be overlooked, that the oily principle upon which depends the odour of certain fish, is absorbed from the alimentary canal, and carried into the blood; this is evident from the peculiar flavour of the flesh of certain birds which live upon fish. It is also well known that persons confined for any length of time to a diet of fish secrete a sweat of a rancid smell. It is not, therefore, improbable that certain cutaneous diseases may be produced, or at least aggravated, by such diet; and in hot climates this effect may be less questionable. The priests of Egypt may therefore have been prohibited from eating fish upon just principles, in order that the leprosy might be averted; and the great legislator of the Jews was, no doubt, influ-

enced by some such belief, when he framed his celebrated prohibition. (Leviticus, xi. 9—12.)

It is usual to add various condiments to fish, and many kinds of fish are doubtless thus rendered more digestible, by a necessary stimulus being afforded to the stomach; but rich sauces are ever to be avoided by the valetudinarian. Vinegar and salt, perhaps, form the best additions.

The mode of cooking fish is another circumstance of some importance. Frying them in lard or oil is an objectionable process: in general, the process of boiling is best adapted for rendering them wholesome. Stewed fish, with all the usual additions of glutinous and stimulant materials, are extremely injurious to dyspeptics.

**Birds.**—There exists a great variety in the qualities of the food which is furnished by this class of animals, with regard to nourishment, stimulus, and digestibility: the whiter meat of domesticated birds, as the wings and breasts of chickens, contains less nutriment, and is less digestible than that which is furnished by wild birds, as the partridge, &c.; but the former is, at the same time, less stimulant and heating than the latter. These are the circumstances which are to direct the medical practitioner in his opinion. No general rule for the choice of either species can be established; it must be determined by the particular condition of the patient, and the effect which the aliment is intended to produce. The same observation will apply to the flesh of quadrupeds; that which is dark-coloured and contains a large proportion of fibrin, as venison, &c. is easily disposed of by the stomach, and a large quantity of highly stimulating chyle is produced from it. The whiter meats are, on the contrary, detained longer in the stomach, and furnish a less stimulant chyle. The former, therefore, will be more easily digested by weak persons, while the latter will frequently run into a state of acetous fermentation; but they may, nevertheless, be preferable on many occasions, inasmuch as they impart less stimulus to the general system. We see, therefore, the folly into which many popular writers have fallen, of stating such or such an article as being wholesome or otherwise; as the wholesomeness of an aliment must depend upon its fitness to produce the particular effect which the case in question may require. Van Swieten has justly said, that “to assert a thing to be wholesome, without a knowledge of the condition of the person for whom it is intended, is like a sailor pronouncing the wind to be fair, without knowing to what port the vessel is bound.”

**Farinaceous Aliments.**—The flour of wheat contains three distinct substances; a *mucilaginous saccharine matter*, *starch*, and a peculiar substance, possessing many of the properties of animal matter, termed *gluten*. It is to the quantity of this latter ingredient that wheat flour possesses so decided a superiority over that of barley, rye, or oats, for from these latter grains much less gluten can be extracted. It furnishes by far the best ingredient for making that important article of diet, *bread*; although it may also be made of all the various sorts of grain, as well as of chestnuts, of several roots, and of the potato. We shall first describe the nature of wheaten bread, and then compare it with that produced from

other substances. The first process for rendering farinaceous seeds esculent, is to grind them into powder between mill-stones: the *meal* thus produced is purified from the husk of the seed, or *bran*, by the operation of sifting or *bolting*; and it is then denominated *flour*. This, when mixed with water or milk, undoubtedly possesses the power of nourishing the body; but in this raw state it would not be sufficiently digestible; it would clog the stomach, and oppose those actions which are essential to chymification. The application, however, of heat renders the compound more easy to masticate as well as to digest; whence we find in the earliest history a reference to some process instituted for the purpose of producing this change, although the discovery of the manufacture of bread, simple as it may appear to us, was probably the work of ages. It has been just stated that wheaten flour is the best adapted for making bread, that is to say, *loaf* bread; this depends upon the greater quantity of gluten which it contains, and which operates in a manner to be presently explained. The first stage of this process of *panification* consists in mixing the flour with water, in order to form a paste, the average proportion of which is two parts of the water to three of the flour; but this will necessarily vary with the age and quality of the flour: in general, the older and the better the flour, the greater will be the quantity of water required. This paste may be regarded as merely a viscid and elastic tissue of gluten, the interstices of which are filled with starch, albumen and sugar. If, then, it be allowed to remain for some time, its ingredients gradually re-act upon each other, the gluten probably performing an important part; by its action on the sweet principle, a *fermentation* is established, and alcohol, carbonic acid, and lastly acetic acid, are evolved. If the paste be now baked, it forms a loaf full of *eyes*, like our bread, but of a taste so sour and unpleasant that it cannot be eaten. If a portion of this old paste, or *leaven*, as it is called, be mixed with new-made paste, the fermentation commences more immediately, a quantity of carbonic acid is given off, but the gluten resists its disengagement, expands like a membrane, and forms a multitude of little cavities, which give lightness and sponginess to the mass. We easily, therefore, perceive why flour, deficient in the tenacity which gluten imparts to it, is incapable of making raised bread, notwithstanding the greatest activity may be given to the fermentative process by artificial additions. Where, however, *leaven* has been employed, the bread will be apt to be sour, in consequence of the great difficulty of so adjusting its proportion, that it shall not by its excess impart an unpleasant flavour, nor by its deficiency render the bread too compact and heavy. It is for such reasons that in this country we employ *barm*; a ferment which collects on the surface of fermenting beer. It appears that we are indebted to the ancient Gauls for this practice. In Paris it was introduced about the end of the seventeenth century; the Faculty of Medicine, however, declared it to be prejudicial to health, and it was long before the bakers could convince the public that bread baked with *barm* was superior to that of *leaven*. A great question arose among chemists as to the nature

of this *barm* that could produce such effects, and elaborate analyses were made, and theories deduced from their results; but all these ingenious speculations fell to the ground, when it was found that *barm*, dried and made into balls, would answer every purpose; the bakers imported it in such a form from Picardy and Flanders, and when again moistened, it fermented bread as well as the recent substance. The presence, therefore, of carbonic acid, water, acetic acid, and alcohol, could not be essential, for these ingredients were separated by the process of its preparation. At length it was discovered that gluten, mixed with a vegetable acid, produced all the desired effects; and such is the nature of leaven, and such is the compound to which *barm* is indebted for its value as a panary ferment. After the dough has sufficiently fermented, and is properly raised, it is put into the oven previously heated, and allowed to remain till it is baked. The mean heat, as ascertained by Mr. Tillet, is  $448^{\circ}$ . When the bread is removed, it will be found to have lost about one-fifth of its weight, owing to the evaporation of water; but this proportion will be varied by the occurrence of numerous circumstances which it is not easy to appreciate. Newly-baked bread has a peculiar odour as well as taste, which are lost by keeping: this shows that some peculiar substance must have been formed during the operation, the nature of which is not understood. Bread differs very completely from the flour of which it is made, for none of the ingredients of the latter can be discovered in it; it is much more miscible with water than dough; and on this circumstance its good qualities, most probably, in a great measure depend. It is not easy to explain the chemical changes which have taken place. It appears certain that a quantity of water, or its elements, is consolidated and combined with the flour; the gluten, too, would seem to form a union with the starch and water, and thus to give rise to a compound upon which the nutritive qualities of bread depend.

*Unleavened* bread consists of a mixture of meal and water, formed into a firm and tough cake, made as thin as possible, to favour its drying, and sometimes with the addition of butter, to render it more soluble, friable, and porous; but it renders it sourer, and more apt to produce acidity on the stomach. Of the unleavened sorts of bread, biscuit is by far the best; and in all cases where leavened or fermented bread does not agree, its use cannot be too strongly advocated.

The different sorts of bread to be met with in this country may be considered under three classes: viz. *white*, *wheaten*, and *household*. In the first, all the *bran* is separated; in the second, only the coarser; in the third, none at all: so that *fine bread* is made only of flour, *wheaten* bread of flour and a mixture of the finer bran, and *household* of the whole substance of the grain, without taking out either the coarse bran or fine flour. It is necessary for the medical practitioner to understand these distinctions; for it will be proved that an important dietetic fact is connected with them. The tendency of starch upon the bowels is astringent. Bread, therefore, which is made of the whitest flour is apt to render them costive; but this is counteracted by the presence of *bran*, the scales of which appear to

exert a mechanical influence upon the intestines, and thus to excite them into action.

The French have many varieties of bread, in which eggs, milk, and butter enter as ingredients. They are also in the habit of adding ammonia to the dough; which, during its evaporation in the oven, raises it, and thus adds to its sponginess.

*Barley-bread* has a sweetish but not an unpleasant taste; it is, however, rather viscid, and is less nutritive, as well as less digestible, than wheaten bread. It is common to mix peas-meal with the barley, which certainly improves the bread. *Rye-bread* is of a dark brown colour, and is apt to lie heavy on the stomach; it is also liable to create acescency and purging; but it appears to be highly nutritive. In some of the interior counties of England, where their bread is often manufactured from oatmeal, there is a mode of preparing the meal by making it sour; the bread, instead of being hard, is thus rendered of a soft texture, and from its moderate acidity is wholesome to strong persons: but invalids should, if possible, avoid it. In bread, however, this grain is more usually in an unfermented state, or it is made into flat, thin cakes, which are baked or roasted. It is evident, from the health and vigour of the people who use this grain as a principal article of diet, that it must be very nutritive; but the stomach will require some discipline before it can digest it. In those unaccustomed to such food, it produces heartburn; and it is said to occasion, even in those with whom it agrees, cutaneous affections. In times of scarcity, potatoes have been made into bread; but they contain too much mucilage in proportion to their starch to afford a good article: the bread thus produced is heavy, and apt to crumble into powder; effects which are obviated by mixing a certain quantity of wheat-flour with the potatoes. Rice will also serve the purpose of making very good bread; but, like the potato, it requires the addition of some flour. It is said by some that bread made of different kinds of grain is more wholesome than that made of only one sort, as their qualities serve to correct one another. This is certainly the case with that which is commonly called *brown bread*, and which is made of a mixture of wheat and rye flour; the former, being of a more starchy nature, and apt to produce costiveness, while the latter often proves too laxative: a due proportion of each, therefore, must furnish a desirable compound.

The importance of bread, as an article of diet, will be easily deduced from the principles upon which the digestion of food in the stomach is explained. In addition to its nutritive qualities, it performs a mechanical duty of some importance. It serves to divide the food, and to impart a suitable bulk and consistence to it; it is, therefore, more necessary to conjoin it with articles containing much aliment in a small space, than where the food is both bulky and nutritive. The concentrated cookery of the French is rendered much more wholesome from the large quantity of bread which that people use at their meals. Bread should never be eaten new; in such a state, it swells like a sponge in the stomach, and proves very indigestible. Care should also be taken to obtain bread that has been duly baked. Unless

all its parts are intimately mixed, and the fixed air expelled, it will be apt, in very small quantities, to produce acescency and indigestion.

After stating the advantages of bread, it is necessary to make a few observations upon the evils which it may occasionally produce. In certain diseases it evidently produces a tendency to acidity; we have daily instances of this fact in children, in whom acidity and much alimentary disturbance follow its use. Shebbeare goes so far as to say that the rickets are so common in France only because the quantity of bread given to children is excessive; which, by its acidity, destroys the calcareous substance of the bones, and reduces them to a state of cartilage. This is mere idle speculation, which is in direct variance with the received opinions upon this subject. Where acidity occurs, the bread should be toasted, or well-prepared biscuit substituted.

Much has been said and written upon the subject of the adulteration of bread; but we are inclined to believe that the evils arising from such a practice have been greatly exaggerated. It is certain that the inferior kinds of flour will not make bread of sufficient whiteness to please the eye of the fastidious citizen without the addition of a proportion of alum. It has been also found that unless this salt be introduced into the flour, the loaves stick together in the oven, and will not afterwards separate from each other with that smooth surface which distinguishes the loaf of the baker. This circumstance is probably owing to the action of the alum upon the mucilage of the flour, which it coagulates. It has been said that the smallest quantity that can be employed for these purposes is from three to four ounces to two hundred and forty pounds of flour. It cannot be denied that the introduction of a portion of alum into the human stomach, however small, may be prejudicial to the exercise of its functions, and particularly in dyspeptic invalids. It was found by Mr. E. Davy, of Cork, that bad flour may be made into tolerable bread by adding to each pound from twenty to forty grains of the common carbonate of magnesia.

Besides bread, several other preparations are made by the solidification of flour, such as pudding, pancake, &c. The most digestible pudding is that made with bread or biscuit and boiled flour: *batter* pudding is not so easily digested; and *suet* pudding is to be considered as the most mischievous to invalids in the whole catalogue. *Pancake* is objectionable on account of the process of frying imparting a greasiness to which the dyspeptic stomach is not often reconciled. All *pastry* is also objectionable: we believe that one half at least of the cases of indigestion which occur after dinner-parties may be traced to this cause.

Many persons entertain a strange prejudice in favour of *pudding*, and appear as if they considered it to possess a balsamic virtue, or some property by which the digestion of other aliment is expedited. If ever such a diet has served the valetudinarian, it must have been by excluding less stimulating food, and not by any virtue adherent in the *pudding* itself.

Amongst the farinaceous aliments, the *potato* holds a distinguished rank; but its digestibility greatly depends upon its kind, and the nature of

the cookery to which it is subjected. The species which is known by the name of *waxy* potato should be shunned by the dyspeptic, for it is so indigestible as to pass through the intestines in an unaltered state. The same objection applies to the young or new potato. The mealy kind more readily yields to the powers of the stomach, and affords a healthy nutriment: but to the dyspeptic, we have generally found this vegetable, in all its states, to be injurious; if ever allowed to such patients, it is worthy of remark that *roasting* is preferable to every other form of cookery. The process of *mashing* certainly does not contribute to its digestibility. If boiled, care should be taken that it is not over-done; for in such a case it is deprived of its nutritious qualities.

*Rice* is the general aliment of the people of the East, with whom it answers the same purposes as bread does with us. As it is not much disposed either to acescency or fermentation in the stomach, it furnishes a wholesome aliment when mixed with other food; but if taken in large quantities by itself, from its low degree of stimulant properties, it is apt to remain for a length of time in the stomach: this effect is greatly increased by protracted boiling. Where the stomach is in a state of relaxation and debility, it ought not to be taken without condiment; it is, for this reason, found necessary in the warmer climates to conjoin it with a considerable quantity of warm spices. There formerly existed a prejudice against its use, from a belief that it had a tendency to produce blindness. It is scarcely necessary to state that such an idea has no foundation in truth. It is generally considered as astringent, and is, therefore, a popular remedy for diarrhœa; no astringent principle, however, has yet been discovered in its composition, and it is probable that it owes its virtues on such occasions to the mild and bland mucilage, with which it abounds, shielding the intestines from acrimonious humours.

There are various other aliments in domestic use which owe their qualities to starch, such as *sago*, *tapioca*, *arrow-root*, &c. From the mucilaginous form in which they are usually administered to invalids, they are not so digestible as is generally supposed; but where the stomach rejects more substantial food, they are useful in themselves, as well as proper vehicles for the administration of vinous stimulants.

The leguminous productions, or *pulses*, may be considered as constituting the second division of farinaceous aliment. They differ little from grains, except in affording a more unctuous flour, which forms a milky solution with water, owing to the presence of an oily matter. Although they are highly nutritive, they are certainly more indigestible than seeds, and the bread they afford is apt to occasion flatulence, and to lie heavy on the stomach. The use, therefore, of this species of food is more circumscribed than that of the farinaceous seeds; it is principally confined to the lower classes, and to those possessing strong powers of digestion. In dyspeptic habits they ought on no account to be allowed; the symptoms of uneasiness which they produce in such persons are often alarming: flatulence and colic are the common consequences of their action. Pulses are employed in two very different states; in an

early stage of their growth, when they are succulent; and when all their parts have reached maturity: in the former condition they are frequently acceptable to the stomach; but in the latter they are only calculated for those who have strong digestive powers.

*Peas* form a wholesome and light food when green and young, but when full grown and dry they are very indigestible: in this latter state they contribute, in a remarkable degree, to the generation of gas in the intestines. In the form of pudding they are, if possible, still more objectionable; for, to the bad qualities which depend upon their composition, are thus added those which arise from tenacity of texture. *Beans*, like peas, are comparatively wholesome in their immature state. The *kidney-bean*, being eaten with its pod, is not so flatulent as other pulse: when well boiled, it is easy of digestion, but not very nutritive.

*Nuts* are generally supposed to have constituted the earliest food of mankind; and they still furnish, in some countries, a considerable source of food. In this country they are principally known as an article of the dessert, although on some occasions they are eaten with our food. With regard to composition, the chestnut may perhaps be considered as more nearly allied to the pulse than to the nut tribe, since it affords no oil by expression, and from its farinaceous qualities it may even be made into bread, although it is heavy and indigestible. Its nutritive power must be considerable, since it forms the chief food of the lower orders of the plains in Lombardy; and it has been conjectured that it was the *acorn* so frequently mentioned in ancient history and tradition. When eaten after dinner, an indulgence which can only be conceded to the most robust, it ought to be previously roasted; its digestibility is also increased by being kept for some time after it has been gathered. It is at the same time thus rendered more palatable by the greater evolution of its saccharine principle.

The evils which may arise from the use of the chestnut are still more likely to occur after the ingestion of nuts, for they are more oily, as well as more viscid and glutinous: when eaten, they should always be accompanied with salt; but it would be wise to banish them entirely from our tables.

**Esculent Roots.**—These are of two kinds; those used as food, and those which principally answer the purposes of condiment or seasoning. Under the first division may be classed *turnips*, *carrots*, *parsnips*, *Jerusalem artichokes*, *rudishes*, &c., many of which, it will be seen, are seldom used solely for aliment, but are rather brought to our tables to qualify our animal food. Under the second division may be arranged *onions*, *garlic*, *horse-radish*, &c. It will be necessary to offer a few observations upon the qualities of these several roots.

The *carrot*, from the quantity of saccharine matter which it contains, is very nutritive and slightly laxative; but it also possesses a large proportion of fibrous matter, which in some stomachs prevents the digestion of the root, and it passes through the bowels with but little change: to obviate this effect, it ought to be very thoroughly

boiled, and it should be eaten when young. It appears to have been introduced by the Flemings, in the reign of Elizabeth. The *turnip* is a very excellent vegetable, and, although it has the character of being flatulent, it is less liable to disagree with the stomach than the carrot; it ought, however, to be well boiled, but the watery part separated by pressure. Lord Townshend, secretary to Charles I., was the person who introduced its use into England; but it appears that the ancient Romans, in the best period of their republic, lived much upon this root. The *parsnip* is nutritive and digestible, although many persons dislike it on account of its sweet flavour. The *Jerusalem artichoke* is agreeable, but watery and flatulent; it ought, therefore, never to be eaten without a proper accompaniment of salt and pepper. All the varieties of *radishes* have a pungent and acrid taste, in consequence of a peculiar stimulating matter, which resides in the cortical part of the root. They may be said to contain little else than water, woody fibre, and acrid matter, and cannot, therefore, be very nutritive; they may act as a stimulant, and thus prove useful, but they ought never to be eaten when old, as the quantity of inert matter in such a condition is apt to disagree with the stomach. From the consideration of radishes, we pass, by an easy transition, to that of onions, &c., for they appear to form the connecting link between alimentary roots and those used principally as condiment. The *onion*, however, although classed under this latter division, and must be considered as valuable on account of its stimulating matter, certainly contains a considerable proportion of nourishment. This appears evident in its boiled state, by which process its acrimony is exhaled, and a sweet mucilage separated. Sir John Sinclair says that it is a well-known fact that a Highlander, with a few raw onions in his pocket, and a crust of bread, or some oat-cake, can travel almost to an incredible extent, for two or three days together, without any other sort of food. The French are fully aware of the quantity of nourishment this plan affords; hence the soup *à l'oignon* is considered by them as the best of all restoratives. As a stimulant to the stomach and bowels, the onion, in a raw state, is certainly of value, and this is much enhanced by its diuretic qualities. The leek, garlick, shallot, are of the same species, and possess qualities of the same nature. *Horse-radish* is a warm and pungent root, and is highly valuable to the dyspeptic as a stimulant; it is, perhaps, the best of all condiments for the prevention of flatulence.

**Esulent Herbs.**—In this class are arranged the leaves and stalks of such vegetables as are eaten at table in the form of “greens and salads.” Herbs eaten in a raw state are far less digestible than when cooked. During the heats of summer they are refreshing, and are well calculated to assuage that febrile state which full meals of animal food are known to occasion. Of all these herbs the *water-cress* is the most beneficial; for, by operating in some degree as an aromatic, it promotes digestion, and corrects that tendency to flatulency which other raw vegetables are apt to produce. According to Xenophon, the ancient Persians lived upon water-cresses, which they considered the most wholesome of vegetable pro-

ductions. The *lettuce* is generally eaten with other herbs, in the form of a salad, dressed with oil and vinegar. Some difference of opinion has arisen with respect to the propriety of such additions. Gosse, of Geneva, found that vinegar retarded its solution in the stomach, and oil has been stated by others to render it less digestible. We have generally found such condiments useful, and that dressed lettuce is less likely to ferment in the stomach than that which is eaten without them. Oil is known to have such an effect in checking fermentation, and the vinegar is not found to promote it. The lettuce contains a narcotic\* principle; and the effect of this is, in a great measure, obviated by a vegetable acid: those persons, therefore, who eat lettuce with a view to obtain such effects, ought to take it without vinegar. The digestibility of celery is greatly increased by maceration in vinegar. *Cucumbers* are by far the most unwholesome of all raw vegetables, and should be avoided as poison by dyspeptics.

The vegetables which require to be boiled are the different species and varieties of *colewort*; the value of which does not depend so much upon their nutritive quality as the tenderness of their texture. On this account, the cauliflower and brocoli are the species to be preferred, particularly the younger sprigs of the former. Of the kinds where the leaves only are employed, the Savoy is of a sweeter and more tender texture than the others, particularly its central and upper leaves. The cabbage tribe appear to contain a peculiar essential oil, whence the unpleasant odour of cabbage-water; this matter is liable to produce offensive effects on the stomach: the vegetable should therefore be boiled in two successive waters, in order to free it entirely from the noxious ingredient, and at the same time to render its texture soft and digestible. *Asparagus* is quickly dissolved in the stomach, and, when sufficiently boiled, is not disposed to create flatulence or acidity: along with its mucilage it frequently contains some sweetness, which affords a proof of its nutritive quality. From the peculiar odour which it imparts to the urine of those who eat it, it appears to possess some active matter distinct from its mucilage; and it is generally considered diuretic. *Asparagus* is only wholesome when in an intermediate state between root and plant. When older than this, it is remarkably acrid.

**Fruits.**—These are generally regarded as articles rather of luxury than of food; and were we to form our opinion of their value from their abuse, we should certainly be rather disposed to class them under the head of poisons than of aliments. Nothing can be more mischievous to the invalid than large quantities of apples, pears, and plums, in the form of dessert, after the stomach has been already loaded. But, when taken under other circumstances, they contribute to health, and appear to be providentially sent at a season when the body requires that cooling and antiseptic aliment which they are so well calculated to afford.

Fruits may be arranged under the following heads: stone fruits, the apple species, small-seeded fruits, small berries, and farinaceous fruits.

\* We are told that Galen in the decline of life, suffered much from morbid vigilance, until he had recourse to eating a lettuce every evening, which cured him.

The stone fruits have been denounced as the least digestible species by popular acclamation, but much of the mischief that has been attributed to their use has arisen from the unripe state in which they were eaten. They are, however, certainly less digestible than other species, and more liable to undergo fermentation in the stomach. The hard pulp of certain plums remains also in the alimentary canal for a long time, and is frequently passed without having been materially changed. The ripe peach is the most delicious, as well as one of the most digestible of the stone fruits; the apricot is equally wholesome, but the nectarine is liable to disagree with some stomachs. Cherries are far less digestible; their pulpy texture and skins are not easily disposed of by the stomach; and as the sweetest species contain a considerable excess of acid, they may be objectionable in some cases, and desirable in others. The apple species are not so dilute and watery as the foregoing fruits, and is less apt to pass into a state of noxious fermentation; but its texture is firmer, and on that account it is retained longer in the stomach, and often proves indigestible. The same observations apply to pears, except that, their texture being in general less firm, they are less objectionable. The orange, when perfectly ripe, may be allowed to the most fastidious dyspeptic; but the white, or inner skin should be scrupulously rejected, for it is not more digestible than leather. The small-seeded fruits are by far the most wholesome. Of these the ripe strawberry and raspberry deserve the first rank. The grape is also cooling and antiseptic, but the husks and seeds should be rejected. The gooseberry is less wholesome on account of the indigestibility of the skin, which is too frequently swallowed. The fruits to be classed under the head of small berries are the cranberry, the bilberry, and the red whortleberry. These are rarely eaten, except when baked, and in that state their acescency seldom proves injurious. The farinaceous fruits are universally unwholesome. The melon, which is the principal one, is very apt to disagree with weak stomachs, and should never be eaten after dinner, even by persons in health, without a plentiful supply of salt and pepper.

By cookery, fruit, otherwise unwholesome, may be converted into a safe and useful aliment. Apples, when baked, afford a pleasant repast, and from their laxative properties, are well adapted to certain forms of dyspepsia. Dried fruits, from the quantity of sugar which generally enters into their composition, are very much disposed to ferment and occasion heartburn.

[The following table exhibits the time required for the stomachal digestion of different alimentary substances, in a well-known case, which fell under the care of Dr. Beaumont, and which the writer had an opportunity of seeing. The table is copied from another work, (the writer's *Elements of Hygiène*, 2d edit. Philad. 1844.) The most digestible substances are taken as the standard, which has been arbitrarily fixed at 1000; and accordingly, as *aponeurosis*, the first article in the table, required three hours, whilst *pigs' feet soused*, *rice*, &c. required but one, its digestibility compared with that of these aliments, is as 333 to 1000; and so of the others. It need scarcely be said,

that all such tabular results apply in strictness to the individual concerned only; yet they afford useful comparative views, which, with exceptions depending upon individual peculiarities, may be regarded as approximations applicable to mankind in general.

ALIMENTS.	Form of preparation.	Time required for stomachal digestion.	Ratio of digestibility compared with the most digestible article in the table
		<i>h. m.</i>	
Aponeurosis . . . . .	boiled	3	333
Apples, mellow . . . . .	raw	2	500
Do. sour, hard . . . . .	do.	2 50	352
Do. sweet, mellow . . . . .	do.	1 50	545
Barley . . . . .	boiled	2	500
Bass, striped, fresh . . . . .	broiled	3	333
Beans, pod . . . . .	boiled	2 30	400
Do. and green corn . . . . .	do.	3 45	266
Beef, fresh, lean, rare . . . . .	roasted	3	333
Do. do. do. dry . . . . .	do.	3 30	285
Do. do. steak . . . . .	broiled	3	333
Do. with salt only . . . . .	boiled	2 45	363
Do. with mustard, &c. . . . .	do.	3 30	285
Do. . . . .	fried	4	250
Do. old, hard salted . . . . .	boiled	4 15	235
Beets . . . . .	do.	3 45	266
Brains, animal . . . . .	do.	1 45	571
Bread, corn . . . . .	baked	3 15	302
Do. wheat, fresh . . . . .	baked	3 30	285
Butter . . . . .	melted	3 30	285
Cabbage, head . . . . .	raw	2 30	400
Do. with vinegar . . . . .	do.	2	500
Do. . . . .	boiled	4 30	222
Cake, corn . . . . .	baked	3	333
Do. sponge . . . . .	do.	2 30	400
Carrot, orange . . . . .	boiled	3 15	302
Cartilage . . . . .	do.	4 15	235
Catfish, fresh . . . . .	fried	3 30	285
Cheese, old, strong . . . . .	raw	3 30	285
Chicken, full grown . . . . .	fricasseed	2 45	363
Codfish, cured dry . . . . .	boiled	2	500
Corn, (green) and beans . . . . .	do.	3 45	266
Custard . . . . .	baked	2 45	363
Duck, domesticated . . . . .	roasted	4	250
Do. wild . . . . .	do.	4 30	222
Dumpling, apple . . . . .	boiled	3	333
Eggs, fresh . . . . .	hard boiled	3 30	285
Do. do. . . . .	soft boiled	3	333
Do. do. . . . .	fried	3 30	285
Do. do. . . . .	roasted	2 15	444
Do. do. . . . .	raw	2	500
Do. do. . . . .	whipped	1 30	666
Flounder, fresh . . . . .	fried	3 30	285
Fowls, domestic . . . . .	boiled	4	250
Do. do. . . . .	roasted	4	250
Gelatin . . . . .	boiled	2 30	400
Goose, wild . . . . .	roasted	2 30	400
Heart, animal . . . . .	fried	4	250
Lamb, fresh . . . . .	boiled	2 30	400

\* [Pigs' feet soused, rice, and tripe soused, being the most digestible articles in the table, are estimated at 1000.]

† [In the case of oils, and other substances of similar nature, which undergo little digestion in the stomach, the time merely indicates the period that elapses before they are sent into the duodenum.]

ALIMENTS.	Form of preparation.	Time required for stomach digestion.	Ratio of digestibility compared with the most digestible articles in the table
		<i>h. m.</i>	
Liver, beef's, fresh . . . .	boiled	2	500
Marrow, animal, spinal . .	do.	2 40	375
Meat and vegetables . . .	hashed	2 30	400
Milk . . . . .	boiled	2	500
Do. . . . .	raw	2 15	444
Mutton, fresh . . . . .	roasted	3 15	307
Do. do. . . . .	broiled	3	333
Do. do. . . . .	boiled	3	333
Oysters, fresh . . . . .	raw	2 55	342
Do. do. . . . .	roasted	3 15	307
Do. do. . . . .	stewed	3 30	285
Parsnips . . . . .	boiled	2 30	400
Pig, sucking . . . . .	roasted	2 30	400
Pigs' feet, soused . . . .	boiled	1	1000
Pork, fat and lean . . . .	roasted	5 15	190
Do. recently salted . . .	boiled	4 30	222
Do. do. . . . .	fried	4 15	235
Do. do. . . . .	broiled	3 15	302
Do. do. . . . .	raw	3	333
Do. do. . . . .	stewed	3	333
Potatoes, Irish . . . . .	boiled	3 30	285

Turnips, flat . . . . .	boiled	3 30	285
Veal, fresh . . . . .	broiled	4	250
Do. do. . . . .	fried	4 30	222
Vegetables and meat, hashed . . . . .	warmed	2 30	400
Venison, steak . . . . .	broiled	1 35	631]

OF DRINKS, OR LIQUID ALIMENTS.—As the introduction of solid aliment into the stomach is for the purpose of furnishing materials for the repair of the different textures, so is a supply of liquid matter essentially necessary to replace the fluids which are constantly ejected from the body, during the exercise of its numerous functions. In this point of view, therefore, the drinks ought to be considered as real aliments. The chyme and

the chyle may also require the assistance of some liquid medium to increase the fluidity of the mass, or to favour the absorption of its finer and more nutritive parts. In every point of view, therefore, dilution is an essential operation; and an animal will not only endure the sensation of hunger with more tranquillity than that of thirst, but he will survive longer under the privation of solid than of liquid aliment.

Before we enter upon this part of the subject, it will be necessary that we should offer a few remarks upon the nature of the changes which liquids undergo when introduced into the stomach, and which would appear to be determined by the nature of their composition. The subject teems with curious facts, and is one of much importance to the physician, as it will enable him to appreciate the utility of liquid diet, and to understand the circumstances which should decide its preference.

It was long supposed that liquids, like solids, passed through the pylorus into the intestines, and were absorbed together with the chyle, or rejected with the excrement. It is not asserted that this never occurs; but it is evident beyond contradiction that there must exist another passage, although its nature remains obscure, by which liquids can be conveyed to the circulation; for it has been shown that, if a ligature be applied round the pyloric orifice, in such a manner as to obliterate the passage into the duodenum, the disappearance of the liquid from the cavity of the stomach is not so much even as retarded. In order to discover whether drinks are absorbed along with the chyle, M. Magendie made a dog swallow a certain quantity of diluted spirit during the digestion of his food; in half an hour afterwards the chyle was extracted and examined: it exhibited no trace of spirit, but the blood exhaled a strong odour of it, and by distillation yielded a sensible quantity.

If a liquid, holding nutritive matter in solution, be introduced into the stomach, it is either coagulated by the gastric juice, or its watery part is absorbed, and the solid matter deposited in the stomach; in either case the solid product is converted into chyme. Milk, as we formerly observed, appears to be the only liquid aliment which Nature has prepared for our nourishment; but it seems that she has, at the same time, provided an agent for rendering a certain portion of it solid, and hence we are led to infer that this form is an indispensable condition of bodies which are destined to undergo the processes of chymification and chyification; and that, unless some provision had existed for the removal of fluids from the stomach, the digestive functions could not have been properly performed. When the broth of meat is introduced into the stomach, the watery part is carried off, and the gelatine, albumen, and fat are then converted into chyme. Wine and fermented liquors undergo a similar change; the alcohol which they contain coagulates a portion of the gastric juice, and this residue, together with the extractive matter, gum, resin, and other principles which the liquid may contain, is then digested. Under certain circumstances these liquids may observe a different law of decomposition, which will, perhaps, in some measure explain the different effects which such potations will

produce; for example, the spirit may undergo a partial change in the stomach, and be even digested with the solid matter, or, on some occasions, be converted into an acid by a fermentative process; this will be more likely to occur in vinous liquors, which contain ingredients favourable to the production of such a change, and hence the deleterious property of fermented liquors does not bear an unvarying relation to the absolute quantity of their alcohol. Oil, though possessing the fluid form, does not appear to observe the law which governs the disposal of such bodies; it is not absorbed, but is entirely transformed into chyme by the stomach. To effect this change, however, it seems essential that the stomach should be in a state of high energy, or the fluid will undergo chemical decomposition; nor will the stomach, unless it be educated, as it were, to this duty, like those of some northern nations, digest any considerable quantity of it; and since it cannot be absorbed, it must find its exit through the alimentary canal, and consequently prove laxative.

In classing the different species of drinks, we may, as with solids, arrange them according to their chemical composition, thus—

I. WATER.—Spring, river, well-water, &c.

II. THE JUICES AND INFUSIONS OF ANIMAL AND VEGETABLE SUBSTANCES.—Whey, tea, coffee, &c.

III. FERMENTED LIQUORS.—Wine, beer, &c.

IV. THE ALCOHOLIC LIQUORS, OR SPIRITS.—Alcohol, brandy, rum, &c.

**Water.**—The qualities of water differ essentially according to the source from which it has been obtained; and those accustomed to this beverage are sensible to differences which wholly escape the observation of less experienced judges. How far the existence of foreign matter injures its salubrity has been a subject of much controversy. That the presence of very minute quantities of earthy matter can become a source of disease sounds strangely to the ears of the philosopher; and yet we have known patients, after drinking a glass of water, from a sense of weight and oppression at the stomach, at once pronounce the existence of foreign ingredients. Animals would appear to be generally more sensible of such impurities than man. Horses, by an instinctive sagacity, always prefer *soft*\* water; and when, by necessity or inattention, they are confined to the use of that which is *hard*, their coats become rough and ill-conditioned, and they are frequently attacked with gripes. Pigeons are also known to refuse hard, after they have been accustomed to soft water. We are informed by Cleghorn that on the eastern side of the island of Minorea, the sheep, on ac-

count of the hardness of the water, are subject to a disease in the spleen. But the most dangerous sources of impurity exist in the animal and vegetable kingdoms; putrescent matter poisons our beverage, and becomes the secret cause of numerous complaints. The usual varieties of common water were classed and defined by Celsus, and modern chemists have not found any reason to reject the arrangement. "*Aqua levissima pluvialis est; dein fontana, tum ex flumine, tum ex puteo; post hæc ex nive aut glacie, gravior his ex lacu, gravissima ex palude.*"

We may remark of river water, that, as it is derived from the conflux of numerous springs and rain water, the proportion of its saline constituents ought to be small, since various precipitations must necessarily take place from the union of different solutions. It is, however, liable to hold in suspension particles of earthy matter which impair its transparency, and not unfrequently its salubrity. It may also, in the vicinity of a large town, hold dissolved, as well as suspended, a considerable portion of animal and vegetable matter: this is unquestionably the case in the water supplied from the Thames by the Grand Junction Water-Company.

For the purification and preservation of water, numerous ingenious methods have been adopted. The mechanical impurities may be easily enough removed by filtration, a process which is suggested by Nature herself, for all springs arising through sand, gravel, &c. must undergo such an operation; but it will not remove a particle of that matter which is held in solution, and hence the filter is only of partial utility. As that peculiar property which constitutes what is termed *hardness* generally depends upon *sulphate of lime* in solution, it cannot be removed by filtration, but the addition of an alkaline carbonate, in the proportion of from ten to fifteen grains, to every pint, twenty-four hours before it is used, will be found to soften it; or, if it should be found to depend upon *super-carbonate of lime*, which is sometimes the case, long ebullition, without any addition, will be found sufficient for its cure. Another mode of improving water, and one which has been lately adopted by Mr. Robins in his patent filters, is by the application of charcoal, a substance which possesses in an eminent degree the property of preserving water from corruption, and of purifying it after it has been corrupted; hence the filtration of water through alternate layers of sand and charcoal offers the readiest and most effectual mode of abstracting its impurities with which we are acquainted.† Where we have reason, however, to suspect much injurious contamination, the process of boiling should never be omitted; after which it may be strained and filtered, and lastly agitated in contact with the atmosphere, in order to restore to it its natural proportion of air. In China, water is never drunk until it has been boiled. The mischievous effects of impure water, where it cannot be corrected by any chemical process, are said to be best counteracted by some bitter vegetable. Virey supposes that this circum-

\* An important practical distinction has been founded upon the fact, that the water of some springs will dissolve soap, while that of others decomposes and curdles it; the former has been denominated *soft*, the latter *hard* water. Sulphate of lime is generally the salt which imparts this quality of hardness; and it appears that the proportion of five grains to the pint is sufficient for the purpose. Soft water is a more powerful solvent of all vegetable matters, and is consequently to be preferred for domestic as well as medicinal use. The brewer knows well, from experience, how much more readily and copiously *soft* water will dissolve the extractive matter of his malt; and the housewife requires not the chemist to inform her that *hard* water is incapable of making good tea.

† The great desideratum has ever been to remove soluble matters from water; it is by no means impossible that a simple voltaic apparatus will hereafter be contrived for such a purpose.

stance first induced the Chinese to infuse the leaves of the tea-plant.

Water is unquestionably the natural beverage of man; but any objection against the use of other fluids founded on their artificial origin, may be at once met by the same argument which has been adduced in defence of cookery. We are to consider man as he is, not as he might have been had he never forsaken the rude path of nature. We are ready to admit that the more simply life is supported, and the less stimulants we use, the better; and that he is happy who considers water the best drink, and salt the best sauce; but how rarely does a physician find that his patient has regulated his life by such a maxim! He is generally called upon to reform stomachs already vitiated by bad habits, and which cannot, without much discipline, be reconciled to simple and wholesome aliment. Under such circumstances, nothing can be more injudicious than abruptly to withdraw the accustomed stimulants, unless it can be clearly shown that they are absolutely injurious,—a question which it will be our duty to investigate.

The juices and infusions of vegetable and animal matter constitute the second division of drinks.

**Toast-Water.**—By impregnating water with the soluble parts of toasted bread, we shall obtain a liquid which will frequently agree with those stomachs which rebel against the use of the more simple fluid. It is thus also rendered slightly nutritive, holding a certain portion of gum and starch in solution. Sir A. Carlisle recommends that it should be prepared with hard biscuit, reduced by fire to a coffee colour. "This drink," says he, "being free from yeast, is a most agreeable beverage. Much depends upon the water, employed for its preparation, being at a boiling temperature, and it ought to be drunk as soon as it has sufficiently cooled; for, by being kept, it acquires a mawkish and unpleasant flavour. Infusions of other kinds of bread, especially those of toasted oat-cakes, and dried or toasted oatmeal, have been recommended; but the taste of such infusions would not be palatable to any one who has not been accustomed to oat-bread.

**Barley-Water.**—The decoction of barley is a very ancient beverage; it is recommended by Hippocrates, and preferred by him to every other aliment in acute diseases. Barley has the advantage over other grains, in affording less viscid potations. The invention of *pearl barley* has greatly increased the value of this grain; it is prepared by the removal of its husk or cuticle, and afterwards by being rounded and polished in a mill. These well-known granules consist chiefly of fecula, with portions of mucilage, gluten, and sugar, which water extracts by decoction; but the solution soon passes into the acetous fermentation. The bran of barley contains an acrid resin, and it is to get rid of such an ingredient that it is deprived of its cuticle. The addition of lemon-juice and sugar-candy greatly improves the flavour of this drink.

**Gruel.**—Oats, when freed from their cuticle, are called *groats*; in which state, as well as when ground into meal, they yield to water, by coction, the fecula they contain, and form a nutritious

gruel, which has also the property of being slightly aperient. It should never be kept longer than forty-eight hours, as it becomes acescent after that period. Gruel may be made of a different degree of consistence, according to the object of its potation. If it be used as a demulcent drink, it should be thin; and may be made, as Dr. Kitchener, our culinary censor, informs us, by mixing well together, by degrees, in a pint basin, *one* table-spoonful of oatmeal with three of cold water, and then adding carefully a pint of boiling water, which is to be boiled for five minutes, stirring it all the time, to prevent the oatmeal from burning at the bottom of the stewpan; then strain through a hair sieve, to separate the undissolved parts of the meal from the gruel. If a more substantial repast is required, double the above quantity of oatmeal must be treated in a similar manner. To increase the nutritive quality of this aliment, broth or milk may be substituted for water. Some persons are in the habit of introducing a piece of butter into gruel; but the propriety of this practice is questionable, where the stomach is supposed to generate acidity.

**Sage Tea.**—The virtues of sage have been so extravagantly praised, that, like many of our remedies, the plant is fallen into disuse from the disgust which its panegyrists have excited. We are convinced, however, that in the form of infusion it possesses some power in allaying the irritability of the stomach, (it is frequently used by the Chinese as a tonic for debility of the stomach,) and that, on many occasions, it will furnish a salutary beverage. The same observation will apply to the infusions of *baln* and *rose mary*. A drink extremely agreeable to the stomach of invalids may also be made by infusing lemon-peel in boiling water, and adding a small quantity of sugar.

**Tea.**—There is no subject that has occasioned a greater controversy amongst dietetic writers than that of tea. By one party it is decried as a poison; by another it is extolled as a medicine, and a valuable addition to our food; while some refer all its beneficial effects to the water thus introduced into the system, and its evil consequences to the high temperature at which it is drunk. In order to understand the value of the different arguments which have been adduced in support or to the disparagement, of this beverage, it will be necessary to inquire into its composition. Two kinds of tea are imported into this country, distinguished by the epithets *black* and *green*. Both contain astringent and narcotic principles, but in very different proportions; the latter producing by far the most powerful influence upon the nervous system. As the primary operation of every narcotic stimulant, tea is found to exhilarate and refresh us, although there exist individuals who are so morbidly sensible to the action of certain bodies of this class, that feelings of depression, accompanied with various nervous sensations and an unnatural vigilance, follow the potation of a single cup of strong tea; while others experience, from the same cause, symptoms indicative of derangement of the digestive organs: but these are exceptions\* from which no general rule ought

\* The reader is referred to a pamphlet entitled "*Observations on the Medicinal and Dietetic Properties of*"

to be deduced. The salubrity of the infusion to the general mass of the community is established by sufficient testimony to outweigh any argument founded on individual cases. It must, however, be admitted, that if this beverage be taken too soon after dinner, the digestion of the meal may be disturbed by the distension it will occasion, as well as by its influence as a diluent; the narcotic and astringent principles may also operate in arresting chymification; but when a physician gives it his sanction, it is with the understanding that it shall be taken in moderate quantities, and at appointed seasons. In enumerating the advantages of tea, it must not be forgotten that it has introduced and cherished a spirit of sobriety; and it must have been remarked by every physician of general practice, that those persons who dislike tea, frequently supply its place by spirit and water. The addition of milk certainly diminishes the astringency of tea; that of sugar may please the palate, but cannot modify the virtues of the infusion.

**Coffee.**—The hostility which has been manifested against the use of tea has been extended, with equal rancour, against that of coffee, and, probably, with equal injustice. The principle upon which its qualities depend is more stimulant than that of tea, and certainly exerts a different species of action upon the nervous system, although it is very difficult to define the nature of this difference. If taken immediately after a meal, it is not found to create that disturbance in its digestion which has been noticed as the occasional consequence of tea; on the contrary, it accelerates the operations of the stomach, and will frequently enable the dyspeptic to digest substances, such as fat and oily aliment, which would otherwise occasion much disturbance. The custom of taking coffee immediately after dinner, so universally practised by the French, no doubt must counteract the evil effects which the peculiar form of their diet is calculated to produce. Coffee, like tea, has certainly an antisoporific effect on many individuals; it imparts an activity to the mind which is incompatible with sleep; but this will rarely occur if the beverage be taken for several hours before our accustomed period of repose. It seems to be generally admitted that it possesses the power of counteracting the effects of narcotics; and hence it is used by the Turks with much advantage, in abating the influence of the inordinate quantities of opium they are accustomed to swallow. When our object is to administer it as a promoter of digestion, it should be carefully made by infusion; decoction dissipates its aroma. The addition of milk is one of questionable propriety; that of sugar, or rather sugar-candy, may be allowed. Some persons can never take this beverage without suffering from acidity in the stomach: where this happens, the practice must be abandoned.

*Green Tea*, by W. Newnham, Esq. There is a great deal of sound sense in this little production. The author refers the different effects produced by green tea to the different states of the system in which it is taken. He maintains that in a state of what he calls *sthenic excitement* of the brain and nervous system, as that produced by alcoholic stimulants, or by intense and long-continued application of the mind to any particular object of literary search, green tea will act as a salutary remedy; whereas, on the contrary, in states of diminished excitement, morbid vigilance and nervous disturbance will follow its potation.

[It appears from recent investigations of organic chemists, that *Theine*, the peculiar principle of tea, and *Caffeine*, the principle of coffee, are identical. "We shall never certainly," says Liebig, (*Animal Chemistry*, edit. cit. p. 169,) "be able to discover how men were led to the use of the hot infusion of the leaves of a certain shrub (tea), or of a decoction of certain roasted seeds (coffee). Some cause there must be, which would explain how the practice has become a necessary of life to whole nations. But it is surely still more remarkable, that the beneficial effects of both plants on the health must be ascribed to one and the same substance, the presence of which in two vegetables, belonging to different natural families, and the produce of different quarters of the globe, could hardly have presented itself to the boldest imagination. Yet recent researches have shown, in such a manner as to exclude all doubt, that caffeine, the peculiar principle of coffee, and theine, that of tea, are, in all respects, identical." And he adds (p. 170): "Without entering minutely into the medicinal action of caffeine (theine), it will surely appear a most striking fact, even if we were to deny its influence on the process of secretion, that this substance, with the addition of oxygen and the elements of water, can yield taurine, the nitrogenized compound peculiar to bile."]

**Chocolate.**—In consequence of the large quantity of nutritive matter which this liquid contains, it should be regarded rather as food than drink. It is prepared by reducing the cocoa-nut into paste, with sugar, milk, or eggs: it is also frequently mixed with different aromatics, the most common of which is the *vanilla*, a substance very liable to disagree with the stomach, and to produce a train of nervous symptoms. As a common beverage, chocolate is highly objectionable; it contains an oil which is difficult of assimilation; it therefore oppresses the stomach: this effect is of course increased by the application of too much heat in its preparation. Another objection against its use is to be found in the observations which we have already offered upon the subject of too great concentration.

**Cocoa** is usually considered as a substitute for chocolate. As it contains less nutritive matter, it is not so objectionable; and, as the oily matter exists only in small quantities, it is less likely to disagree with the stomach.

There are certain saline solutions which are frequently employed as drinks, and deserve some attention in this place: such are *imperial* and *soda water*. *Imperial* is a solution of cream of tartar flavoured with lemon-peel. It ought never to be used except as a medicine. If employed as an ordinary drink, it is apt to retard digestion. If ever useful as an article of diet, it will be under circumstances of robust health, and where a large quantity of animal food has been taken. The modern custom of drinking *soda water* during, or immediately after dinner, has been a pregnant source of dyspepsia. By inflating the stomach at such a period, we inevitably counteract those muscular contractions which are essential to chymification. The quantity of soda thus introduced scarcely deserves notice: with the exception of the *carbonic acid gas*, it may be regarded as water, more mischievous only in consequence of

the exhilarating quality inducing us to take it at a period at which we should not require the more simple fluid.

**Fermented Liquors.**—Volumcs have been written to prove that spirit, in every form, is not only unnecessary to those who are in health, but that it has been the prolific source of the most painful and fatal diseases to which man is subject; in short, that Epimetheus himself did not, by opening the box of Pandora, commit a greater act of hostility against our nature than the discoverer of fermented liquors. This is a striking specimen of the fallacy of reasoning against the *use* of a custom from its *abuse*. There exists no evidence to prove that a temperate use of good wine, when taken at seasonable hours, has ever proved injurious to healthy adults. In youth, and still more in infancy, the stimulus which it imparts to the stomach is undoubtedly injurious; but there are exceptions even to this general rule. The occasional use of *diluted* wine has improved the health of a child, by imparting vigour to a torpid stomach: we ought, however, to consider it rather as a medicine than as a luxury.

Without entering further into the discussion of a question which has called so many opponents into the field, it may be observed that whatever opinion we may have formed as to the evils or advantages consequent upon the invention of wine, we are not called upon, as physicians, to defend it; our object is to direct remedies for the cure of those diseases which assail man as we find him in the habits of society. And as these habits, says Dr. W. Philip, are such that more or less alcohol is necessary to support the usual vigour of the greater number of people even in health, nothing could be more injudicious than wholly to deprive them of it when they are already weakened by disease, unless it could be shown that even a moderate use of it essentially adds to their disease, which, in dyspeptics, is by no means the case. Our own experience coincides with that opinion. In cases where the vinous stimulant has been withdrawn, we have generally witnessed an aggravation of the dyspeptic symptoms, accompanied with severe depression of spirits.

The term wine is more strictly and especially applied to express the fermented juice of the *grape*; although in common language it is used to denote that of *any* sub-acid fruit. The presence of *tartar* is perhaps the circumstance by which the grape is more strongly distinguished from all the other sub-acid fruits that have been applied to the art of wine-making. Its juice, besides, contains within itself all the principles essential to vinification, in such a proportion and state of balance as to enable it at once to undergo a regular and complete fermentation; whereas, the juices of other fruits require artificial additions for this purpose: and the scientific application and due adjustment of these means constitute the art of making domestic wines.\* It has been remarked that all those wines which contain an excess of malic acid are of a bad quality: hence the grand

defect that is necessarily inherent in the wines of this country, and which leads them to partake of the properties of cider; for in the place of the *tartaric*, the malic acid always predominates in our native fruits.

The characteristic ingredient of all wines is *alcohol*; and the quantity of this, and the condition or state of combination in which it exists, are the circumstances that include the more interesting points of inquiry, and explain the relative effects which different wines produce upon the system; we shall therefore proceed to investigate the various species, with reference to such conditions.

Wines may be at once resolved into two great divisions; into those which are coloured, and commonly called *red* wines, and into those which have a yellow tinge, more or less deep, termed *white* wines. This colouring matter is not derived from the juice, but from the husk of the grapes. If, therefore, the fermentation be not permitted to take place in contact with the hulls, and sometimes even with the stalks of the fruit, a *white* wine is in all cases produced. This colouring matter is highly astringent, and consequently the red wines differ from the white in their effects upon the stomach; and yet it is difficult to explain the well-known extent of this operation by the presence of so small a proportion of active matter. It must, however, be remembered that irritable stomachs are frequently impatient of astringent matter. Many persons are incapable of drinking port wine in consequence of the heart-burn it occasions; while others, on the contrary, appear to derive advantage from the tonic influence of its astringency. This is a circumstance of idiosyncrasy which no theory can explain. Every physician must be practically aware of the caprice which the stomach displays in its morbid conditions; but as a general rule, it may be stated that *white* deserve a preference over *red* wines, because the latter, being pressed, and subjected to a stronger fermentation to extract the colouring principle from the husk, are necessarily more loaded with extractive and astringent matter; and as this remains in the stomach after the liquid portion of the wine is absorbed, it will be liable to occasion disturbance.

The odour, or *bouquet*, and flavour which distinguish one wine from another, evidently depend upon some volatile and fugacious principle not hitherto investigated by the chemist: this, in sweet and half-fermented wines, is immediately derived from the fruit, as in those from the *Frontignan* and *Muscat* grapes; but in the more perfect wines, as in *Claret*, *Hermitage*, *Rivesaltes*, and *Burgundy*, it bears no resemblance to the natural flavour of the fruit, but is altogether the product of the vinous process. Some wines are artificially flavoured by the introduction of foreign ingredients, as by almonds in Madeira wines, as well as in those of Xeres and St. Lucar; and hence their well-known nutty flavour. Among the ancients, and in modern Greece, it is at this day the fashion to give a resinous flavour, by the introduction of turpentine into the casks. These wines were supposed to assist digestion, to restrain morbid discharges, to promote urine, and to strengthen the bowels; but Dioscorides informs us that thev

\* For an account of which, the reader is referred to a most ingenious and interesting essay by Dr. Macculloch, entitled "Remarks on the Art of making Wine; with Suggestions for the Application of its Principles to the Improvement of Domestic Wines."

were known to produce vertigo, pain in the head, and many evils not incidental to the potations of the same vinous liquor when free from such admixtures.

The quantity of acid contained in wines has been supposed capable of diminishing their salubrity, and in some cases of rendering them eminently noxious. There can be no doubt that where there exists a considerable excess of gallic or malic acids, or where acetic acid has been generated during a protracted fermentation, such wine will be obnoxious to the stomach; but where the acid arises from the nature of the fruit, it surely cannot merit the odium which popular opinion would assign to it. What, for instance, is the acid contained in Madeira, and against which so many objections have been urged? an atom merely of tartar! And yet the person who fancies that his digestion can be deranged by its action, will swallow twenty times the quantity of the same ingredient in some other shape with perfect indifference and impunity.

Before we quit the subject of vinous acidity, we must add a few words upon its supposed influence in exciting paroxysms of gout. That such attacks have followed particular potations we do not mean to deny; but a slight excess of any kind, whether in diet or in exercise, will excite the disease in those predisposed to it. Where this predisposition exists, an additional glass of claret may excite the disease; but in all such cases any other exciting cause would have a similar effect.

It has been already stated that the characteristic ingredient of all wines is *alcohol*; and that its quantity, and the condition or state of combination in which it exists, are the circumstances in which the medical inquirer is principally interested. The late experiments of Mr. Brande have thrown considerable light upon this subject; although, as in most instances of discovery, they have raised up new doubts and difficulties. Daily experience convinces us that the same quantity of alcohol applied to the stomach under the form of wine, and in a state of mixture with water, will produce very different effects upon the body, and to an extent which it is difficult to understand. It has, for instance, been demonstrated beyond the reach of doubt, that port, madeira, and sherry contain from one-fourth to one-fifth of their bulk of alcohol; so that a person who takes a bottle of any one of them will thus take nearly half a pint of alcohol, or almost a pint of pure brandy! And, moreover, that different wines, although containing the same absolute proportion of spirit, will be found to vary very considerably in their intoxicating powers. No wonder, then, that such results should have staggered the philosopher, who is naturally unwilling to accept any tests of difference from the nervous system, which elude the ordinary resources of analytical chemistry. The conclusion was therefore drawn, that alcohol must necessarily exist in wine in a far different condition from that in which we know it in a separate state; or, in other words, that its elements only could exist in the vinous liquor, and that their union was determined, and, consequently, alcohol produced, by the act of distillation. That it was the *product*, and not the *educt* of distillation, was an opinion which originated with Rouelle, who

asserted that alcohol was not completely formed until the temperature was raised to the point of distillation. More lately, the same doctrine was revived and promulgated by Fabbioni, in the Memoirs of the Florentine Academy. Gay Lussac has, however, silenced the partisans of this theory, by separating the alcohol by distillation, at the temperature of 66° Fahrenheit; and, by the aid of a vacuum, it has since been effected at 56°. And to complete the demonstration, Mr. Brande has shown that, by precipitating the colouring matter, and some other elements of the wine, by the *sub-acetate of lead*, and then saturating the clear liquor with *sub-carbonate of potash*, the alcohol may be separated without any elevation of temperature; and he has accordingly, by this ingenious expedient, been enabled to construct a table, exhibiting the proportions of spirit which exist in the several kinds of wine. No doubt, therefore, can any longer be entertained upon the subject; and the fact of the difference of effect produced by the same bulk of alcohol, when presented to the stomach in different states, is to be explained on the supposition that, in wine, it is not only more intimately mixed with water, but that it exists in combination with its extractive matter; in consequence of which it is incapable of exerting its full effects before it becomes altered in its properties, or, in other words, partially *digested*; and this view of the subject may be fairly urged in explanation of the fact, that the intoxicating effects of the same wine are liable to vary in degree in the same individual, from the peculiar state of his digestive organs at the time of its potation.

We have hitherto only considered alcohol as it exists in a combined state in wine; but it is essential to state that the stronger wines of Spain, Portugal, and Sicily, are rendered marketable in this country by the addition of *brandy*, and must consequently contain more or less *uncombined* spirit; but the proportion of which will not bear a ratio to the quantity added, because, at the period of its admixture, a renewed fermentation is produced by the scientific vintner, which will assimilate and combine a certain portion of the foreign spirit with the wine: this manipulation, in technical language, is called "*fretting in*." It is to the quantity of *free*, not to that of *combined* spirit, that the injurious effects of such wines are to be attributed! "It is well known," observes Dr. Macculloch, "that diseases of the liver are the most common and the most formidable of those produced by the use of *ardent* spirits." It is equally certain that no such disorders follow the intemperate use of *pure* wine, however long indulged in: to the concealed and unwitting consumption of spirit, therefore, as contained in the wines generally drunk in this country, is to be attributed the excessive prevalence of those hepatic affections, which are comparatively little known to our continental neighbours.

Much has been said about the effects of *new* wine upon the stomach, compared with those produced by that which has been long kept. It will be necessary to consider the changes produced in this liquor by being kept. In the first place, red wine gradually deposits a quantity of cream of tartar, in combination with extractive and colour-

ing matter, forming what is commonly called the crust; so that a considerable portion of that matter which is likely to disagree with the stomach is thus removed; but when kept in a cask, in addition to this change, a quantity of water is evaporated, and the wine becomes comparatively stronger. The custom of exposing Madeira to motion, and a certain elevation of temperature, by sending it a voyage to the East Indies, unquestionably improves the flavour, and produces some internal change in the composition of the wine, which the chemist is unable to explain.

In a dietetic point of view, wines may be arranged into four classes; viz. 1, *sweet wines*; 2, *sparkling or effervescing*; 3, *dry and light*; 4, *dry and strong*.

1. *Sweet wines* contain the greatest proportion of extractive and saccharine matter, and generally the least ardent spirit, though it is often rather disguised than absent. Since a proportion of sugar has remained unchanged in these wines during the process of vinification, they must be considered as the results of an imperfect fermentation, and are, in fact, mixtures of wine and sugar; accordingly, whatever arrests the progress of fermentation must have a tendency to produce a sweet wine. Thus, boiling the *must*, or drying the fruit, will, by partially separating the natural leaven, and dissipating the water, occasion such a result as is exemplified by the manufacture of the wines of Cyprus, the *Vino Cotto* of the Italians, and the *Vinum Coctum* of the ancients; by that of *Frontignac*, the rich and luscious wines of *Canary*, the celebrated *Tokay*, *Vino Tinto* (Tent of Hungary), the Italian *Montefiascone*, the Persian *Schiraz*, the *Malmsey* wines of Candia, Chio, Lesbos, and Tenedos, and those of the other islands of the Archipelago. On account of the sugar contained in such wines, they are liable to become accepsent on weak stomachs; but where this is not the case, they are, in small quantities, frequently beneficial to invalids.

2. *Sparkling or effervescing wines*.—These are indebted for their characteristic properties to the presence of carbonic acid; they rapidly intoxicate, in consequence of the alcohol which is suspended in, or more probably, in chemical combination with the gas, being thus applied in a sudden and very divided state to a large extent of nervous surface: for the same reason their effects are generally as transitory as they are sudden. Independently of the alcohol thus held in solution in the carbonic acid, it is probable that some active aromatic matter is volatilised together with it, and which may account for the peculiar effects produced on some persons by champagne.

3. *Dry and light wines*.—These are exemplified by the more esteemed German wines, as hock, rhénish, mayne, moselle, neckar, and elsass; and those highly-flavoured wines, burgundy, claret, hermitage, &c. The former of these wines combine the effect of an acid with that of the spirit. They do not contain any uncombined alcohol, and on that account are to be greatly preferred. *Genuine claret* must be considered as the most beneficial of all our vinous liquors; it is well fermented; and on account of the small proportion of spirit, as well as of extractive, which it contains, it is more salubrious than port. It has been

already observed that burgundy appears to hold dissolved some unknown principle of great activity; upon no other supposition can we explain its stimulant properties. A few glasses of this wine will produce heat and headach, which the relative quantity of alcohol in its composition will not account for.

4. *Dry and strong wines*, as madeira, port, sherry, &c. The name *sec*, corruptly written sack, signifies dry. The *sec wine*, prepared at Xeres, in Spain, is called, according to our orthography, sherris or sherry. In the manufacture of this wine, *lime* is added to the grapes; a circumstance, observes Dr. Macculloch, apparently conducive to its well-known dry quality, and which, probably, acts by neutralizing a portion of *malic* or *tartaric* acid.

It is a fact not easily explained, that the stomach is frequently outraged by a wine to which it has not been accustomed; and it is equally true that a mixture of different wines is a common source of indigestion. The custom of mixing wine with water has its advantages as well as its evils. By dilution it frequently proves too little stimulant to the stomach, and runs into a state of acescency. An invalid is also thus liable to deceive himself, by taking more wine than may be consistent with his welfare. Much, however, depends upon the quality of the wine taken; the lighter wines cannot require dilution, while port is certainly rendered less injurious by the admixture.

Home-made or domestic wines may be generally considered as injurious to delicate stomachs; they are apt to ferment and produce indigestion. Cider and perry are grateful drinks in hot weather; but as they do not contain a sufficient quantity of spirit to prevent their passing into the acetous fermentation in the stomach of an invalid, they should be avoided by those who have any predisposition to indigestion.

*Beer*.—This is an article of beverage in almost every country. The Chinese prepare it from rice, and the Americans from maize. We are also informed by Herodotus, that, in very early history, the art of making a fermented liquor from barley was discovered by the Egyptians. As the climate of England is not congenial to the growth of the vine, this species of liquor is perhaps more universal than in any other country; and it has therefore been denominated *vinum Britannicum*. In the higher walks of society, it has, indeed, of late years, been nearly excluded: but whether this revolution has been attended with advantage, we shall presently have occasion to inquire. Malt liquors differ from wines in several essential points: they contain a much larger proportion of nutritive matter, and a less proportion of spirit; while they contain a peculiar bitter and narcotic principle derived from the hop. It would appear that the extractive matter furnished by the malt is highly nutritive; and we accordingly find that persons addicted to such potations are in general fat. Where, however, they are indulged in to any extent, without a corresponding degree of exercise, they induce a plethoric state of the body, and all the diseases consequent upon such a condition. In order to understand the process by which they furnish nourishment, we must once more refer

the reader to the observations which are offered on the important subject of the digestion of liquids; from which it will appear that highly-concentrated extract will be left in the stomach after the removal of its watery part. This extract is, for reasons already stated, not very digestible; and will therefore require the presence of less inspissated food to promote its chymification. Ale, therefore, when taken without such precautions, is liable to disturb the digestive organs. The addition of the hop increases the value of the liquor, by the grateful stimulus which it imparts, and in some measure redeems it from those vices with which it might otherwise be charged. To those therefore whose diet is not very nutritive, ale may be considered not only as an innocent but as a salubrious article; and happy is that country whose labouring classes prefer such a beverage to the mischievous potations of ardent spirit. These remarks cannot, however, apply to the classes of the community who "fare sumptuously every day." They will not require a nutritive potation of such a character; and light wines have accordingly, in these days of luxury, very properly superseded its use: but we are not disposed to extend this remark to its more humble companion, "*table beer*." We regard its dismissal from the tables of the great as a matter of regret; its slight but invigorating bitter is much better adapted to promote digestion than its more costly substitutes. But it should be soft and mild; for when stale and hard it is likely to disturb the bowels, and occasion effects the very opposite to those it is intended to produce. Nor ought it to have too great a proportion of hops, but should be thoroughly fermented and purified. Sydenham always took a glass of small beer at his meals, and he considered it as a preservative against gravel.

The great division of malt liquors is into small beer, ale, and porter.

The liquor called *Ale* was originally made of barley, malt, and yeast alone. There existed for a long time a strong prejudice against hops, which were considered as "pernicious weeds;" but it is now generally admitted that they constitute the most valuable ingredient in malt liquors. Independently of the flavour and tonic virtues which they communicate, they precipitate, by means of their astringent principle, the vegetable mucilage, and thus remove from the beer the active principle of its fermentation: without hops, therefore, we must either drink our malt liquors new and rosy, or old and sour. There are several varieties of ale, distinguishable by their colour: when the malt is slenderly dried, the ale is *pale*; or *brown* when the malt is more roasted or high dried.

*Porter*.—This is made from high-dried malt, and differs from other malt liquors in the proportions of its ingredients, and by the peculiar manner in which it is manufactured. Much has been said upon the fraudulent adulteration of this article; but we are inclined to believe that these statements have been exaggerated.

*Ardent Spirits*.—The art of extracting alcoholic liquors by distillation from vinous liquors, must be regarded as the greatest curse ever inflicted upon human nature. The fatal effects of dram-drinking have been vividly depicted by numerous writers; and the awful truth has been too fre-

quently illustrated to render any remarks in this place necessary. In a medical point of view, however, spirit may be considered as occasionally useful. Where it is taken in a diluted state, the mixture should always be made twelve hours before it is used. Spirit and water do not easily combine; and much of the force of the former is blunted by intimate incorporation with the latter, as we have already observed under the history of wine. We throw out this hint to those who are in the habit of drinking weak brandy and water at their meals: although the propriety of such a practice is questionable. There are cases of dyspepsia in which wine and beer equally disagree with the stomach, producing acidity and other distressing symptoms: very weak spirit may, perhaps, in such cases, be taken with advantage; but its strength should be uniform, and no circumstances should induce the patient to increase the proportion of the spirit. The habit of drinking *liqueurs* cannot be too much reprobated: many of these *cordials* are impregnated with narcotic substances, which add to the noxious qualities of the spirit.

*OF CONDIMENTS*.—These may be defined substances which are, in themselves, incapable of nourishing the body, but which, in concert with our food, heighten its flavour, promote its digestion, or correct some of its deleterious properties. The existence and necessity of such agents are more general and important than is generally supposed, and a philosophical examination of their *modus operandi* would disclose views of great and novel interest to the physician. The bitter principle which exists in the composition of grasses and of other plants, appears to be essential to the digestive process of herbivorous animals, for when deprived of it they become diseased; and yet we are assured, by repeated experiment, that it passes through the alimentary canal without undergoing the least change; it can therefore only act as a stimulant *in transitu*, and affords an excellent example of a natural condiment. We are ourselves conscious of the invigorating effects of slight bitters upon our stomach, although civilization has, to a great degree, destroyed our natural taste for them, while, by improving our vegetable food, it has probably rendered such a stimulus unnecessary. The Swiss peasant cheers himself amid the frigid solitude of his glaciers with a spirit distilled from *gentian*, the extreme bitterness of which is relished with a glee that is quite unintelligible to those who are not accustomed to it.

From the different nature of condiment, it has been usually divided into three classes, viz. the *saline*, the *spicy* or *aromatic*, and the *oily*.

*Salt* appears to be a necessary and universal stimulus to animated beings; and its effects upon the vegetable as well as animal kingdom have furnished objects of the most interesting inquiry to the physiologist, the chemist, the physician, and the agriculturist. It appears to be a natural stimulant to the digestive organs of all warm-blooded animals, and they are instinctively led to immense distances in pursuit of it. This is strikingly exemplified in the avidity with which animals in a wild state seek the salt-pans of Africa and America, and in the difficulties they will encounter to reach them: this cannot arise from accident or

caprice, but from a powerful instinct, which, beyond control, compels them to seek at all risks that which is salubrious. We are all sensible of the effect of salt on the human body; we know how unpalatable fresh meat and most vegetables are without it. One of the ill effects produced by an unsalted diet is the generation of worms. In Ireland, where from the bad quality of the food the lower classes are greatly infested with worms, a draught of salt and water is a popular and efficacious anthelmintic. Lord Somerville, in his Address to the Board of Agriculture, gave an interesting account of the effects of a punishment which formerly existed in Holland. "The ancient laws of the country ordained men to be kept on bread alone, *unmixed with salt*, as the severest punishment that could be inflicted upon them in their moist climate. The effect was horrible; these wretched criminals are said to have been devoured by worms engendered in their own stomachs." The wholesomeness and digestibility of our bread are undoubtedly much promoted by the addition of the salt which it so universally receives.\*

If the utility of salt be thus established, it may be asked how it can happen that salted provisions should ever produce those diseases which experience has shown to arise from their use. In explaining the operation of *salting* meat, and in appreciating the effects of such meat as food, it will be necessary to advert to a chemical fact, which has not hitherto attracted the attention which its importance merits. The salt thus combined with the animal fibre ought no longer to be considered as condiment; a chemical combination has taken place; and although it is difficult to explain the nature of the affinities which have been brought into action, or that of the compound to which they have given origin, it is sufficiently evident that the texture of the fibre is so changed as to be less nutritive as well as less digestible. If we are called upon to produce any chemical evidence in support of such an assertion, we need only relate the experiment of M. Eller, who found, that if salt and water be boiled in a copper vessel, the solution will contain a notable quantity of that metal; whereas if, instead of heating a simple solution, the salt be previously mixed with beef, bacon, or fish, the fluid resulting from it will not contain an atom of copper. Does not this prove that the process of salting meat is something more than the mere saturation of the animal fibre with muriate of soda?

*Vinegar*, in small quantities, is a grateful and wholesome stimulant; it will often check the chemical fermentation of certain substances in the stomach, and prevent vegetable matter in its raw state from inducing flatulence; but its use requires caution, and in some morbid states of the system it is obviously improper. Fatty and gelatinous substances frequently appear to be rendered more digestible in the stomach by the addition of vinegar, although it is difficult to offer either a chemical or physiological explanation of the fact. The native vegetable acids may also be occasionally

substituted: the addition of lemon-juice to rich and glutinous soups renders them less liable to disagree with the stomach; and the custom of eating apple-sauce with pork is, undoubtedly, indebted for its origin to the same cause. We shall take this opportunity to observe that vinegar, if taken in considerable quantities, as is not unfrequently the case with young persons, to prevent the accumulation of fat, is highly injurious to the digestive organs; and, if the habit be long continued, produces fatal marasmus.

The *aromatic condiments* comprise the foreign spices, as pepper, cayenne pepper, cinnamon, nutmeg, cloves, ginger; and the indigenous herbs and roots, such as parsley, thyme, sage, garlic, leek, onion, horse-radish, mustard, &c. The former of these were not intended by nature for the inhabitants of temperate climes: they are heating and highly stimulant. We are, however, not anxious to give more weight to this objection than it deserves. Man is no longer the child of nature, or the passive inhabitant of any particular region: he ranges over every part of the globe, and elicits nourishment from the productions of every climate. It may be therefore necessary that he should accompany the ingestion of foreign aliment with foreign condiment. If we go to the East for tea, there is no reason why we should not go to the West for sugar. The dyspeptic invalid, however, should be cautious in their use; they may afford temporary benefit at the expense of permanent mischief. It has been well said that the best quality of spices is to stimulate the appetite, and their worst to destroy by insensible degrees the tone of the stomach. The intrinsic goodness of meats should always be suspected when they require spicy seasoning to compensate for their natural want of sapidity. But, mischievous as the abuse of aromatic condiments may be, it is innocent in comparison with the custom of swallowing a quantity of brandy or an increased libation of wine to counteract the distress which supervenes on a too copious meal.

*Oil*.—This, with butter, constitutes what are called the oleaginous condiments. Melted butter is, perhaps, the most injurious of all the inventions of cookery: oil, when used in extremely small quantities, as a seasoning to salads, appears to prevent their running into fermentation, and consequently obviates flatulency.

## II. ON THE PERIODS BEST ADAPTED FOR MEALS, AND ON THE INTERVALS WHICH SHOULD ELAPSE BETWEEN EACH.

Having offered a history of alimentary substances, and pointed out the general characters by which each species may be distinguished, we shall, in the next place, proceed to inquire into the various circumstances which may be capable of modifying the effects of food upon the human body, so as to promote, retard, or altogether to suspend the digestion of it; and first, with regard to the periods best adapted for meals. It is not extraordinary that a discrepancy of opinion should exist upon a question which involves so many fluctuating circumstances. Controversy upon this, as upon many other subjects of diet, has engendered a disbelief in its importance, and this scepticism has given a plausible pretext for indulgence on the one hand, and protracted fasting on the other,

\* A pound of salt is generally added to each bushel of flour. Hence it may be presumed, that every adult consumes two ounces of salt per week, or six pounds and a half per annum, in bread only.

as the wishes or habits of mankind may have rendered most agreeable. We have been told that the best time for dining is, "*for a rich man, when he can get an appetite, and for a poor man, when he can get food.*" But appetite in health is regulated by habit, and in disease it acts but as an imperfect monitor. Certain general principles, therefore, deduced from observation and experience, must be laid down for our guidance, and these again in their application must be modified and adapted to the circumstances of every particular case; but before we enter upon this part of our subject, we must offer a few remarks upon the phenomena of *hunger* and *thirst*.

To account for the well-known sensation of hunger, various hypotheses have been framed, which it is not our present purpose to examine. The physiologists of the present day would appear to incline to the belief that it arises from the stimulant action of the gastric juice upon the nerves of the stomach; and to support this opinion, Dr. Wilson Philip relates the following experiment. A person in good health was prevailed upon to abstain from eating for more than twenty-four hours, and during that interval to increase the appetite by more than ordinary exercise. At the end of this time he was extremely hungry; but, instead of eating, he excited vomiting by drinking warm water and irritating the fauces. The water returned mixed only with a ropy fluid, such as the gastric juice is described to be. After this operation, not only all desire to eat was removed, but a degree of disgust was excited by seeing others eat. He, however, was prevailed upon to take a little bread and milk, which in a very short time ran into the acetous fermentation, as indicated by flatulence and eructation. Now, if this experiment proves anything, it merely shows that disturbance of the stomach, or of the nervous arrangements which are subservient to it, will destroy appetite for food; the existence of nausea, short of vomiting, will produce the same effect, and yet in this latter case the gastric juice is not removed: so, again, if a narcotic be applied to the nerves, their power is paralyzed, and the sensation of hunger ceases. Such an effect is produced by the juice of tobacco, although by long habit the stomach may become indifferent to its operation. Whenever the Indians of Asia and America undertake a long journey, and are likely to be destitute of provisions, they mix the juice of tobacco with powdered shells in the form of small balls, which they retain in their mouths, the gradual solution of which serves to counteract the cravings of hunger. Sir Walter Scott tells us that "General Monk, not being able to procure any supper at Coltstream, was fain to have recourse to chewing tobacco to appease his hunger." In like manner we may explain the operation of spirit in taking away the appetite of those who are not accustomed to it; while those who indulge the habit receive its stimulant without its narcotic impression. Lord Byron entertained a great dread of becoming corpulent, and on that account frequently abstained from food for several days together, appeasing his hunger by a wafer and a glass of brandy.

Although we do not mean to deny that the presence of a portion of gastric juice does not con-

tribute to the sensation of hunger, it is quite evident that the phenomenon is intimately connected with an energetic state of the nerves, occasioned by an interval of inactivity, during which, when the organs are in a healthy condition, the vital powers may be supposed to accumulate. We might even venture to question the agency of the stomach so far as to contend that the sensation of hunger is seated in the ganglionic system; for we know from actual experiment that *nausea* is wholly independent of the stomach, since that sensation, as well as the spasm of retching, may be produced by the injection of tartar emetic into the veins of an animal, from which the stomach has been previously removed. Nausea, then, although, like hunger, it be referred to the stomach, is evidently independent of it; and if nausea can exist, why may not the opposite sensation of hunger, even though the animal should have lost its stomach by excision?

Natural appetite, which is only the first degree of hunger, never appears to recur until the aliment previously introduced has been duly assimilated. It cannot, therefore, strictly speaking, be said to have an immediate reference to the state of the stomach; for although all the chyme may have long before passed out of that organ, if any delay or embarrassment occur in its ulterior changes, appetite will not return, since the nervous energy being engaged in their completion cannot accumulate in the stomach; on the contrary, in certain diseases, as in *tabes mesenterica*, notwithstanding the presence of alimentary matter in the stomach, the appetite is never pacified, the subsequent processes being imperfect. These views are not introduced in this place for the purpose of encouraging fruitless speculation, but in order to establish a proposition of the highest importance in its relations to the theory of diet; viz. *that the several processes by which food is converted into blood cannot be simultaneously performed without such an expenditure of vital energy as weak persons are unable to sustain without mischief.* Thus, chylification would appear to require the quiescence of the stomach, and sanguification to be still more incompatible with the act of chymification. If, therefore, the stomach be set to work during the latter stages of digestion, the processes will in weak persons be much disturbed, if not entirely suspended. Certain circumstances cause hunger to return at nearer intervals by accelerating the nutritive process; while others, by producing an opposite tendency, lengthen such intervals.

It is a well-known fact that if a person be interrupted in his meal for a quarter of an hour, he finds on resuming it that his appetite is gone, although he may not have eaten half the quantity which he required; this probably arises from the food having entered upon those ulterior changes which are incompatible with the energy of the stomach.

The feeling of thirst announces to the individual the necessity of introducing a certain quantity of liquid into the system, in order to repair the waste which the body has sustained in the exercise of its functions, or to impart a due degree of solubility to the aliments which have been taken. We accordingly find that excessive perspiration

increases the demand for it, and that dry food is followed by the same effect. The sensation is usually referred to the throat and fauces, but its intensity does not bear any relation to the dryness of those parts; for in some cases, where the tongue, to its very root, is covered with a thick and dry crust, there is little thirst; while, on the other hand, it is frequently intolerable at the very time the mouth is surcharged with saliva. We are inclined to refer the sensation to the cardiac or splenic portion of the stomach.\* Dr. Gardner has remarked that, in the case of a person who had cut through the œsophagus, several buckets-full of water were swallowed daily, and discharged through the wound, without quenching the thirst, which was afterwards found to abate by the injection of diluted spirits into the stomach.

All physicians advocate the necessity of regularity, both as regards the number of meals, and the periods at which they are taken. Those who have weak stomachs will, by such a system, not only digest more food, but will be less liable to those affections which arise from its imperfect assimilation; because, as Dr. Darwin has justly observed, they have in such a case both the stimulus of the aliment they take, and the periodical habit to assist the process. The periods of hunger and thirst are undoubtedly catenated with certain portions of time, or degrees of exhaustion, or other diurnal habits of life; and if the pain of hunger be not removed by taking food at the usual time, it is liable to cease until the next period of time or other habits recur. As these periods must vary according to circumstances in each individual, it frequently becomes necessary in civilized life to have recourse to intermediate meals, or luncheons; but to the dyspeptic patient such indulgences are rarely to be permitted. It is the more necessary to impress this precept upon the minds of invalids, as the anxiety of friends and the popular errors which exist upon the subject are too apt to establish the mischievous though specious aphorism of Sir William Temple, that "the stomach of an invalid is like a schoolboy, always at mischief unless it be employed." By such a system the natural process of digestion must, if our preceding views be correct, be constantly disturbed, and the healthy action of the stomach, as evinced by the return of moderate appetite, entirely prevented. But though the advantage of regular meals at stated periods is desirable, it has been much disputed how many ought to be allowed in the day: some physicians have considered one, others two, three, or even five necessary. It is, perhaps, impossible to lay down a general rule that shall apply to every particular case. In some persons the food rarely remains longer than three hours in the stomach; in others four, five, or even six hours. It is evident, then,

that the repetition of the meals ought to be regulated by this circumstance; always avoiding the extreme of long fasting and repletion. Celsus recommends the healthy to take food rather twice than once in the day, and Sanctorius says, "that the body becomes more heavy and uneasy after six pounds taken at once than after eight taken at three meals," and that he who makes but one meal in the day, let him eat much or little, is pursuing a system that must ultimately injure him. When Plato returned that memorable answer to the philosophers who inquired whether he had seen any thing remarkable in Trinacria, "*vidi monstrum in natura, hominem bis saturatum in die*," he referred rather to the quantity than to the repetition of the meal of Dionysius. In our opinion, where the individual takes moderate exercise, three frugal meals may be allowed. It is reported that, when Alexander the Great turned away his cooks on proceeding upon a march, he observed that he had no further occasion for such assistants, as he carried with him superior cooks—a long morning's journey to create an appetite for his dinner, and a frugal dinner to give a relish to his supper.

**Breakfast** is, perhaps, the most natural and not the least important of our meals: for, since many hours must have intervened since the preceding repast, the stomach ought to be in a condition to receive a fresh supply of aliment. As all the food in the body has during the night been digested, we might presume that a person in the morning ought to feel an appetite on rising; this, however, is not always the fact: the energies of the stomach, although invigorated by repose, are not immediately called into action, especially in debilitated habits; it is therefore frequently advisable to allow an interval to pass before the meal. A question of some interest has arisen as to the propriety of taking a solid or liquid breakfast. We seem to have greatly departed from the custom of our hardy ancestors in this respect. A maid of honour in the court of Elizabeth breakfasted upon beef and drank ale after it; while the sportsman and even the day-labourer of the present day frequently breakfasts upon tea. The periods of their meals, however, were so generally different from those of modern times, that we cannot establish any useful comparison between them without taking into consideration the collateral circumstances which must have influenced their operation. It will not be difficult to show that liquids at this meal are essentially necessary. To say nothing of the instinctive desire we all feel for them, it is evident that there is a certain acrimony and rankness in all our secretions at that time; the breath has frequently a peculiar taint in the morning, which is not perceptible at subsequent periods of the day. The fluids of the body must have sustained a loss by perspiration, which experiments have shown to be double during sleep, a fact which in itself shows the propriety of a liquid breakfast.

**Dinner.**—Among the Romans this was rather considered as a refreshment to prevent faintness, than as a meal to convey much nourishment; but in modern times we need scarcely say that it is regarded as the principal meal, at which every species of luxurious gratification is indulged in.

\* Although the stomach is a single bag, it may be considered, with respect to its functions, as divisible into two distinct cavities; and these portions are, during the activity of the stomach, separated from each other by a peculiar muscular contraction. These chambers evidently appear to perform different offices in the process of digestion. The splenic portion would seem to separate from the food the superabundant water, and then to transmit the former to the pyloric division, where it undergoes its first great change. In the horse the mucous membranes of the two extremities of the stomach present even a striking difference of structure.

With regard to the proper period at which invalids should dine, physicians entertain but one opinion. This period is the middle of the day, or at about two or three o'clock, in order to afford a timely replenishment before the evening waning of the vital powers, and which naturally precedes the hour of rest. The exact period, however, of dinner must in some measure be directed with reference to the necessary habits of the patient, the nature and time of his breakfast, and, above all, to the rapidity or slowness of his digestion.

*Ought we to take liquids at our dinner?*—This question has been a fruitful source of controversy; but it appears to us to be very easily settled. By drinking *before* a meal, we place the stomach in a very unfit condition for the duties it has to perform. By drinking *during* a meal, we shall assist digestion if the solid matter be of a nature to require it, and impede it if the quantity taken renders the mass too liquid. It is evident that if the stomach be distended with fluid, the digestion of its solid contents must meet with impediment; its bulk will stimulate the muscular fibres to contract too rapidly, and thus to expel the food before it has undergone the necessary changes; while at the same time, if the solid matter be diffused through a large quantity of liquid, it cannot be so easily acted upon by the gastric juice; nor can it be readily converted into that pulsatious mass which appears to be a preliminary step to its digestion. On the other hand, if the food be too hard or dry, its necessary change by the *churning* of the stomach cannot be accomplished. It therefore follows that different aliments will require different quantities of liquid to assist their chymification. Animal food will demand, of course, a greater quantity than vegetable food; roasted than boiled meat, &c. The best, and perhaps the only test of the necessity of liquid during dinner is to be found in the sensations of the individual, which ought never to be disregarded because they appear in opposition to some preconceived theory. If our food possess that degree of succulence which characterises digestible aliment, there will seldom be any occasion for drink; but, on the contrary, where the mass is too dry, the stomach will give us notice of it by the creation of thirst. But, under any circumstances, the quantity taken should be small; it is during the intervals of our solid meals that the liquid necessary for the repair of our fluids should be taken: and this brings us to the consideration of the next repast.

**Tea.**—Theory and experience both conform in demonstrating the advantage which attends a liquid repast a few hours after dinner. At this period the chyle has entered its proper vessels, and is flowing into the blood, in order to undergo its final changes. Then it is that the stomach, having disposed of its charge, receives the wholesome draught with the greatest advantage; then it is that the blood, impregnated with new materials, requires the assistance of a diluent to complete their sanguification, and to carry off the superfluous matter; and it is then that the kidneys and the skin will require the aid of additional water to assist the performance of their functions.

**Supper.**—In the time of Elizabeth, the no-

bility and gentry were accustomed to dine at eleven, to sup between five and six, and to retire to rest at ten. It is therefore evident that any argument in favour of this meal, founded upon the healthy condition of our ancestors, cannot avail. By supper, in modern times, we mean a meal just before bed-time; but as sleep is not favourable to every stage of digestion, it is very questionable whether retiring to rest with a full stomach can, under any circumstances, be salutary. During the first part of the process, or that of chymification, a person so situated may perhaps sleep quietly, unless, indeed, the morbid distension of the stomach should impede respiration, and occasion distress; but when the food has passed out of the stomach, and the processes of chylification and sanguification have been established, the natural propensity of the body is for activity, and the invalid awakes at this period, and remains in a feverish state for some hours. Upon this general principle, then, suppers, that is to say, *hearty* suppers, are to be avoided. The same objection cannot be urged against a *light* repast, which is often useful to dyspeptics; and it has been truly and facetiously observed, that some invalids need not put on their night-cap if they do not first bribe their stomachs to good behaviour.

**On the quantity of Food that ought to be taken at different meals.**—Nothing can be more absurd than to establish a rule of weight and measure upon such occasions. Individuals differ from each other so widely in their capacities for food, that to attempt the construction of a universal standard would be little less absurd than the practice of the philosophical tailors of Laputa, who, the reader will remember, wrought by mathematical calculation, and entertained a supreme contempt for those humble and illiterate fashioners who went to work by measuring the person of their customer; but Gulliver tells us that the worst clothes he ever wore were constructed on abstract principles. How then, it may be asked, shall we be able to fix the proportion of food which it may be proper for an invalid to take? By desiring the patient to attend carefully to the first feeling of satiety. There is a moment when the relish given by the appetite ceases; a single mouthful taken after this oppresses a weak stomach. If he eats slowly, and carefully attends to this feeling, he will never overload the stomach; but, that such indication may not deceive him, let him remember to *eat slowly* and to *masticate* thoroughly. This is an important condition; for when we eat too fast, we introduce a greater quantity of food into the stomach than the gastric juice can at once combine with; the consequence of which will be, that appetite may continue after the stomach has received more than it can well digest.

**On the conduct to be pursued previous and subsequent to Meals; and on the regulations of Diet to the Non-naturals.**—We do not intend to assert that Nature ever contemplated the necessity of confining men to a certain routine of habits; nor did she ever contemplate, as far as we can learn, the existence of those diseases which may render such discipline necessary. We have in this place only to inquire into the habits which are most favourable or hostile to the

process of digestion, and then to form a code for the direction of those who may stand in need of such artificial assistance. We have therefore to consider the influences of air, exercise, sleep, and the passions of the mind.

Exercise in the open air is essential to the well-being of every one; but its degree must be regulated by circumstances. The interval between breakfast and dinner is the period for active exertion, and the enjoyment of it, when not attended with severe fatigue, will strengthen and invigorate all the functions of the body; but it is important to remark that *the valetudinarian and dyspeptic should never take his principal meal in a state of fatigue*: and yet what habit is more general? Every body is impressed with the belief that after the sedentary occupation of the morning, to take a long and fatiguing walk will sharpen the appetite and invigorate the digestion: the consequence is obvious; instead of curing, such a practice is calculated to perpetuate and even to aggravate a dyspeptic malady; for the powers of digestion will be thus summoned at a period when the vital energy of the body is exhausted. We are anxious to be clearly understood upon this point: let it not, therefore, be supposed that we decry the use of moderate exercise before dinner; it is only the abuse of it we are so anxious to prevent. No person should sit down to a full meal unless he has previously inhaled the open air, and taken a quantity of exercise proportionate to his power of sustaining it without fatigue.

If exercise be necessary previous to a meal, there is also a certain period after it at which the accomplishment of the last stage of digestion will be accelerated by it.

When the chyle enters the blood, the body becomes enlivened; while the stomach and small intestines, having been liberated from their burthen, oppose no obstacle to the free indulgence of that desire for activity which Nature has thus instinctively excited for our benefit. Then it is that animals are roused from that repose into which they had subsided during the earlier stages of digestion, and betake themselves to action; then it is that civilized man feels an aptness for exertion, although he mistakes the nature and object of the impulse, and is inclined to regard it as nothing more than a healthy sensation, by which he is summoned to that occupation to which inclination or duty may prompt him. Thus, instead of being *bodily* active, the studious man receives it as a summons to mental exertion; the indolent man, perhaps, merely to sit up and enjoy himself; the libertine to commence his libations; and the votary of fashion to attend the crowded circles of gaiety and dissipation. In short, this feeling of renovated energy is used or abused in a thousand ways by different individuals, without their ever dreaming that *bodily exercise*, and *that alone*, is implied by it. The result of this mistake is, that imperfect assimilation and all its train of evils follow. In this respect our ancestors enjoyed a great advantage from their early hours; they were enabled by them to take exercise at the most advantageous periods of the day; even the ball-room, which in our days might be termed Death's ante-chamber, was not injurious;—with them the dance commenced at six and ter-

minated at eleven; with us it begins at eleven and ends at six!

If exercise be useful during the period of sanguification, pure air is not less so; and we may take this opportunity of protesting against the custom of frequenting crowded and ill-ventilated apartments at the very hour when the body requires the purest air for the sanguification of the aliment which has been recently taken into it.

Sleeping after dinner is a practice of very questionable propriety: it is true that the inhabitants of many southern climates indulge in it with impunity; but it does not appear essential in this country, where animal food is used in such considerable quantities. Its effect is to hurry on the different stages of digestion; and hence the fever and state of excitement in which the person not unfrequently awakes. In states of disease, it may occasionally be useful, and the recumbent posture may expedite the passage of the aliment out of the stomach; but we should recommend those who indulge in such a habit to remove all ligatures from the body.

Passions of the mind, such as fear, anxiety, and rage, are well known to affect the nervous system, and, through that medium, the stomach and functions of the digestive organs; and so immediately are their consequences experienced, that a person receiving unpleasant intelligence at the hour of repast is incapable of eating a morsel, whatever might have been the appetite before such communication.

"Read o'er this;  
And after this; and then to breakfast  
With what appetite you may."

In directing our attention to the *excretions*, we must not overlook the sympathy subsisting between the skin and stomach. If the cutaneous vessels be universally excited, and this excitation be long continued, they will at length fall into a state of indirect debility, whence a sense of faintness, loss of appetite, and the inability of digesting solid food will be experienced. This fact explains the diminished appetite of which persons complain in hot weather, and that universal custom in tropical climates of combining the food with large quantities of aromatic stimulants. One of the most striking instances indicative of this consent between the skin and the stomach is to be found in cases where cold or wet has been applied to the lower extremities. The following is an extract from a letter received by the writer of this article, from Dr. John Badeley, of Chelmsford:—"A gentleman who consulted my father, complained that on getting out of bed in the morning, and putting on his leather breeches, he constantly vomited, from the sensation of cold thus occasioned. My father recommended him to take a glassful of cold water before he commenced dressing, and it was found effectual. The gentleman never afterwards vomited upon these occasions."

But it is necessary to conclude this essay. We have endeavoured, in the shortest possible compass, to develop the philosophy of the subject of dietetics, and, as far as our present knowledge extends, to point out the chemical and physical varieties of structure and composition which confer upon different articles of nourishment their rela-

tive, nutritive, and digestible qualities. In the article *REGIMEN* we shall endeavour to apply this knowledge to the treatment of individual diseases. No general rule can be given for the guidance of the physician in such cases. Every such attempt must be a failure: it may foster quackery, and perpetuate popular error, but it can never advance the progress of that pure and simple science which it is the object of these pages to inculcate.

J. A. PARIS.

**DILATATION OF BRONCHI.**—See *BRONCHITIS, CHRONIC.*

**[DILATATION OF THE HEART.**—See *HEART, DILATATION OF THE.*]

**DISEASE.** Disease is disordered action of any part of the machinery of the body, [or it is, an altered condition of structure, or function, or both, in some part of the organism.] Its primary effects, or perhaps we would say, its primary palpable phenomena, are impeded or disordered functions; and of these the results are alterations of structure, and various symptoms or signs indicative of functional and of structural changes.

There is a state of the different systems of which the body is composed, in which all the functions of life are performed with comfort and ease, and a sense of well-being. This is the state of health. Whenever any bodily or mental function is not performed thus harmoniously, there is an interruption of this state, however slight the departure from the condition of health may be. The first symptom of this slight disease, for such it is, is mere discomfort. As the disorder proceeds, if it does proceed, from this slight beginning, the discomfort is succeeded by pain and various other circumstances, which are all consequently so many symptoms of disease. Thus the slightest disordered action may produce only inconvenience; as nausea, vertigo, pruritus: and increased disordered action will produce increased inconvenience; vomiting, loss of sense, cutaneous inflammation, with the additional symptoms of pain. On this aggravated state changes of structure supervene. It occasionally happens that functional disorders, because they in such cases affect parts of a low degree of sensibility, proceed far, even to structural alteration, with nothing more than symptoms of occasional discomfort; but these instances are not frequent.

Compatible with the state of health, also, are considerable varieties in the performance of certain functions. They do not interrupt health so far as to produce even discomfort. The pulse of some individuals is never beyond 50, and of others never below 110. In some the function of digestion is more rapidly and actively performed than in others: and the intellectual alacrity of different persons is well known to be widely different, yet without disease. But when the food is not digested without discomfort or pain, or the circulation not carried on, or the mental movements not made, without similar results; when the appetite is lost, when there is fainting, when there is privation or other affection of any of the sensations or mental faculties; then there is disease.

The least consideration shows us that man is exposed to various circumstances capable of disordering his functions, and all these circumstances

are so many *causes* of disease. They are found in the elements by which he is surrounded; in the food on which he subsists; in excess or defect of voluntary exercise; and in the nature of his mind, sensations, and affections, which subjects him to various kinds of risk by prompting various actions and enterprises, and which is susceptible of impressions as well as capable of originating such actions. Man is also liable to conat and inherited defects, and to diseases resulting from the natural decay of his bodily frame.

The element to which man is chiefly and at all times exposed, is the air. Its variable temperature, dryness, and moisture; its alternations of calmness and commotion; and probably, also, its variable electrical states; not only immediately affect the surface and the respiratory organs, but through the latter the blood, and through that fluid the energy of all parts of the system. Some of the variations seem to have a direct influence on the nervous system; and there are presumable properties in the air, yet unknown save in their destructive effects, which are largely concerned in the production of our common continued fevers, the yellow fever, the plague, the intermittents of fenny countries, cholera, and what is called influenza. No doubt can be entertained of the agency of such atmospherical influences in the production of the common eruptive disorders; and of one at least of the disorders characterised by irritation of a particular portion of the nervous system (the respiratory), and by spasm,—circumstances exemplified by the whooping-cough. The direct influence of the air on the nervous system is not easily proved; but to this, or to some effect produced on the fluids or solids of the body, together or separately, must be ascribed the variations of feeling and spirits experienced by so many individuals in variable states of the weather, and the suicidal despondency which medical travellers have found to be induced by the sirocco. (Dr. J. Johnson.) The condition of certain structures of the body, and perhaps of their nerves, is seen in the course of the seasons to be materially affected by certain states of the atmosphere: the effects being sometimes, apparently, merely the result of temperature, as in the catarrhs, and disorders of the respiratory and circulating apparatus in the cold weather of severe winters; but at other times more obscure, as in the irritability of the mucous membrane of the stomach and intestines in the summer and autumn, of which the consequences are periodical dyspepsia, gastric fevers, diarrhœa, dysentery, and cholera. Of diseases thus obscurely arising, some, peculiar to particular localities, are called endemic; others, appearing and disappearing at particular seasons with some regularity, are called epidemic, and many of the latter become under certain circumstances communicable from one individual to another.

Several of the occupations of man in civilised countries are carried on in confined and ill-ventilated places, where the mere assemblage of many persons deteriorates the quality of the air: the effect of breathing this is very injurious to health, and a very common cause of disease. The influence of a high temperature, combined with excessive moisture, has been abundantly experienced in

the diseases incidental to tropical climates. There are also occupations in the course of which light particles of foreign matter are mingled with the air and inspired; as needle-pointing, grinding of corn, and mason's work; and these particles cause irritation and disease.

In the quality and in the quantity of food are found also the causes of disease. Some kinds of food produce disorder by their stimulating properties, and some by otherwise inducing departures from healthy processes, as in the example of calculous formations in the kidneys. Man is equally disordered by excess and defect of nutrition.

Excess or defect of voluntary exercise and rest affects him no less. It is the rule of nature that voluntary muscular action cannot be neglected with impunity; and its excess produces direct exhaustion.

Many familiar facts, not uninteresting to the medical observer, illustrate the effects of certain species and measures of diet, and peculiar kinds and degrees of exercise, upon the human body. The corpulence and fatness of coachmen and farmers, and the thinness of students and of foot-soldiers, may afford him instruction. But the effects of what is termed *training*, both in increasing and decreasing the bulk and strength of the body, and the vigour of the mind, are more especially deserving of attention. By the administration of dry and very nutritious food; by a certain degree of exercise in the open air; by allowing a moderate portion of sleep; and by avoiding every kind of excess; assisted, however, it should be said, by great attention to the state of the surface, and by a little preparatory purgative medicine; the athlete of old, and the prize-fighters of modern times, have been accustomed to attain such a corporeal condition in the course of six or eight weeks as to endure great fatigue, to breathe freely and fully under extreme exertion, to bear violent blows on the head without giddiness, and to incur severe wounds without danger or long inconvenience. The appetite, after such a system of training, becomes great; the skin becomes of a better colour; and the shape of the body improves. A man thus disciplined can not only run twenty or thirty miles with ease, or walk a hundred, but can face dangers which would before have appalled him; and wrestle or contend advantageously with an assailant by whose strength he would previously have been overpowered. It is said, too, that the perceptions become more acute, and the mental faculties more active; but such consequences are of course not always observed among those who are commonly the subjects of training, although in their gaming devices they not unfrequently show great acuteness and power of calculation. These effects of training are commonly very transient, and repeated or excessive training seems to shorten human life. It is a question, however, how far this supposed hurtful effect of training is to be ascribed to the intemperate habits of the persons usually submitting to training. Race-horses and game-cocks, which are also subjected to particular training, are not found to be shorter-lived than other animals of the same species.

By methods entirely opposite, the reduction of strength and of bulk may be effected in a very

short space of time. The boys employed as jockeys at Doncaster and Newmarket are sometimes reduced twelve or sixteen pounds in weight in the course of ten days, in order to ride a particular race. They are not allowed during this preparation to have meat, or wine, or ale; but live on fish, and puddings, and bread and butter: they have tea at night, but nothing to eat with it. With this slender diet is conjoined strong exercise in thick and heavy clothing. After the race is run, the jockey is allowed to indulge himself; and it is said that as much as nine pounds in weight have been regained in eighteen hours. The effects of this reduction of weight and strength on the brain, as exemplified in the intellectual manifestations, have not been noticed; but it is said that the constitution is often ruined by these vicissitudes. Many jockeys may be observed to be stunted in growth, and to have, even in the prime of life, the dry and withered appearance of premature old age.

It is worthy to be remarked, that not only do excess in diet and extreme abstinence, too much rest and excessive fatigue, extremes of heat and extremes of cold, disorder the body; but that they all seem, when carried to the utmost, to affect the body in the same, or nearly the same manner. All (perhaps by impairing the functions of the nervous and vascular systems) eventually induce those disturbed actions which constitute febrile disorder. In fact, what is called *re-action*, under most circumstances, consists of the establishment of actions tending to febrile or inflammatory processes; and probably the converse, namely, that inflammations and fevers are commonly intended to rid the body of some inconvenience, is not far from the truth.

The great gift of the mind, also, by which man is so greatly raised above the lower animals—by which he inquires, improves, records his improvements, and looks beyond this life—is a gift that his imperfect nature cannot bear without the tribute of occasional inconveniences, from which the less privileged animals are exempt. Its inordinate exertion, and the vehement impressions of which it is susceptible, exhaust the nervous energy, or impair the nervous actions, or alter the actual condition of the nerve; and thus deprive the physical part of the system of some of its power, increase its susceptibility, disturb the processes which should be performed in the different bodily organs, and bring on disease, or gradually enfeeble the whole system. From such causes we perceive, in different cases, various irregular actions, chiefly exemplified in the muscles,—agitation, tremor, faltering voice, unsteady gait, spasm, hysteria, epilepsy;—or exemplifications of diminished power, as in the various shades of paralysis.

By sloth and negligence, or by irregularity and prodigality of application, the powers of the mind itself are equally impaired in some cases, and in others disturbed. Sudden and excessive joy exhausts the mental and nervous power at once; and sudden and overwhelming sorrow oppresses both beyond recovery, producing a state which is sometimes followed by that deep sleep which restores the capacity of endurance, and sometimes by that sleep which ends all worldly suffering.

The influence of sudden mental impressions on

the circulation, in whatever way this is exerted, is evident enough in numerous instances. Their power in the production of that unequal distribution of blood called *determination* is conspicuously seen in the simple act of blushing. Violent anger, or a sense of shame, causes the smaller vessels of the face and neck to be instantaneously injected with blood. By similar, but more violent effects, anger has led to apoplexy; and this passion is seen to render the face red in some individuals and pale in others. Fear commonly produces paleness, and extreme fear may induce death. The functions of the lungs may be affected, or at least the respiratory exertions are quickened, by surprise or other emotion; and simultaneous palpitations show that the heart responds to the same influences; or its sympathy may produce some suspension of its actions, and syncope ensue: the faltering speech and the trembling limbs on some occasions, and the increased speed and strength exhibited on others, equally show how much the muscular energy may be influenced by temporary states of the mind. The gushing of tears in states of sorrow; the diarrhoea and copious renal secretion under the action of fear or vexation; the sudden appearance of gout and of cutaneous eruptions in circumstances productive of great mental disturbance; the profuse perspirations, and the altered colour of the hair sometimes induced; are all illustrations of the operation of the same class of causes.

Long-continued depression of mind, or long anxiety, produces effects which are deeper and less immediately visible. The nervous and the vascular system seem equally to suffer; and habitual disorder of some of the functions, going on to the structural alteration of some organ, is the consequence. Chronic determination to the vessels of the stomach or lungs; or to the liver, or intestines; or to the heart, or to the brain itself, are common results. Obstinate dyspepsia, attacks of asthma, permanent mischief to the hepatic and intestinal functions, or some variety of mental disorder, are among the modes in which such results are manifested: as is also a slow increase in the size, or change in some part of the structure, of the heart itself; curiously according with that strong and melancholy expression, that the person thus destroyed has "died of a broken heart."

On the other hand, need any one be informed of the happy effects of a tranquil state of mind, or of the improved health which is brought by complete relief from heavy anxiety? The amended appetite, the better sleep, the improved complexion, the increased nutrition, which follow in the train of cheerfulness, must be familiar to the most superficial observation.

The diseases produced by a disordered imagination require only to be mentioned.

There is a principle in the human body which enables it, when not previously disordered, to support and resist the influences of all the agents of disease up to a certain point. By this principle, which has been called the conservative principle, it is enabled to endure great and even sudden changes of temperature, and is secured for a time against noxious atmospheric influences. Great variety of food can not only be borne without

inconvenience, but appears to be salutary; and occasional imprudences, as regards both excess and fasting, will, in a state of perfect health, produce no permanent uneasiness. So also exercise may be taken, even to the production of extreme fatigue, or we may devote ourselves to long-continued sedentary study, and yet remain well for a time; and it is familiarly seen that neglect of proper rest often passes unpunished. It is the same with respect to the mind. When we are in perfect health, the various trials met with in the world; the joys, the sorrows, the anxieties, which by turns affect us, are met with steadiness and fortitude, and pass away without disturbing the equanimity of that part of the system on which they make their transient impression. Leisure or complete idleness may also be interchanged with severe or varied mental application, and the health of the mind still be maintained.

But when, by the prolonged or inordinate impression of some of the causes of disease already enumerated, or by other causes of disease which remain to be mentioned, the vital power is impaired in any one organ; when, for instance, the gastric, pulmonary, or cutaneous functions, or the faculties of the mind, begin to show a little interruption of vigour and regularity, even the ordinary objects with which the especial function is habitually concerned become exciting causes of disease. Not only extremes and sudden varieties, but the common air, the ordinary kind and measure of food and drink, the customary exercise, and the daily excitements and depressions of social life, become so many sources of irritation: all those things which have occasionally been defined the sources of vital motion,—all external stimuli, all ideas of the mind, and volition,—then become causes of actual disease.

Besides the causes of disease to which man is by his position constantly exposed, there are others incidental to his frame itself. A heart naturally feeble, or disproportionately small, is inconsistent with health. In every part of the globe, although more in some parts than in others, the species is subject to occasional deformities, some of which, as a contracted cranium or thorax, interfere with the most important functions, and impede their just performance. Very serious diseases arise also, in the course of life, from disordered actions, of which the causes are often entirely unknown; such are those departures from healthy deposition denominated cancer, tubercle, fungus hæmatodes; as well as the production of parasitic animals in certain structures.

It is also very often seen that one disease will produce a second, not unfrequently more severe and dangerous. In this way some of the morbid formations just spoken of are occasionally induced; as that of pulmonary tubercle after a severe attack of catarrh, or after whooping-cough, or fever, or the measles. There is so close a connection between the different functions of the body, and between these and the mind, that no function can be long or very severely disordered without involving the disorder of another. This is particularly observable in affections of the respiratory and circulating systems, but is existent, in a greater or less degree, with respect to all the rest. As fever is a disease which most deeply affects all the functions

of the body, it more than any other leaves a disposition to various forms of disease; sometimes to disease in the organs of locomotion, sometimes to disease of the lungs, and very often to diseases dependent on serious impairment of the nervous system, as paralysis or fatuity. The most numerous instances, however, of disease following disease, are furnished by irritations, various in kind and in degree, of the intestinal mucous membrane; which are so largely concerned in fevers as by some pathologists to be considered as their sole cause, and which doubtless induce every variety of irritation in the vascular apparatus of different tissues, from simple determination to common or to specific inflammation; aggravating also, and often alone producing, all the varieties of nervous and spasmodic affections; and being most widely concerned in the establishment of local disorders of every description, from a simple papular eruption to erysipelas, or to ulceration and deep destruction of parts. The sympathies subsisting between the liver and the brain, and, more remarkably, between the uterus and the whole nervous system, produce phenomena from which the list of illustrations might be greatly swelled.

Some diseases, chiefly such as exclusively affect glands, will in succession attack various parts. When tubercles exist in the lungs, they often also exist in several other situations, as in the mesenteric glands, in the glands of the intestines, in the uterus, in the liver, in the kidneys, even in the heart. The term malignant has been, although with no very settled meaning, applied to such affections, and most frequently to cancer and fungus hæmatodes, which, when once existing in any part, are imagined by some pathologists to spread to other parts, and especially to other glands, by absorption. It is at least certain that such diseases seem to extend themselves in succession from the structure first attacked. The cause is not so clear as the fact is certain. It may be, that a general predisposition existing to a specific form of disease, the absorption, which unquestionably takes place, of diseased matter, acts only by applying an irritant or exciting cause to other parts, as sufficient as other irritants, but not more sufficient than they, to disorder the glands through which it passes; and which glands, when irritated and disordered, run into the disease to which they are by original constitution predisposed. Or the disease may be simultaneous in many parts, although unequally advanced. With respect to tubercles, however, when they exist in other parts of the body than the lungs, it may, we believe, be always predicated that they will also be found in the lungs themselves, and in a more advanced state.

It is not to be forgotten, moreover, that the means employed to cure diseases are not always guiltless of producing others. Nearly every kind of medicine induces a temporary state which is really a state of disease, of which the intention and effect is to relieve diseases more serious or less controllable. The excessive employment, therefore, of any kind of medicine may induce permanent or at least serious disease. Thus drastic purgatives will bring on hemorrhoids; mercury will hasten the progress of phthisis; alkalies will irritate the digestive mucous mem-

brane; and all the narcotics will obtund the sensations and cloud the intellect. There is the strongest reason to believe that many nervous affections are exasperated by the habitual employment of mercurial purgatives; iodine has sometimes caused more obvious nervous irritations; the nitrate of silver produces a permanent disease of the skin, limited, however, to an affection of its colour.

Old age, naturally impairing the vigour of every function, necessarily exposes every function to disorder from common causes. In the best constructed body, the failure of the human frame must begin somewhere. Even in those rare cases in which extreme old age seems to be borne without disease, there is commonly particular impairment of some function or other for some time before all the functions cease. Long before death, the diminution of muscular power generally becomes evident. A marked failure in the powers of the stomach is still more common. The inconveniences of this time of life have, however, been eloquently enumerated in the article AGE.

The terms applied to all these different causes of disease, and the arrangement of them, have occasioned much very useless dispute. It is time that such scholastic trifling should be abandoned. What was defined, we believe first by Gaubius, as the *proximate cause*, which when present constituted the disease, when taken away removed it, and, when changed, changed it, either means nothing, or means the first of the effects of the cause of disease.

Two things are plainly necessary for the production of disease; a cause which acts on some organ, and a disposition in the organ to be acted upon. Two kinds of causes, then, and two only, are plainly concerned in the production of disease; a cause which predisposes, and a cause which excites. This may be illustrated by the single instance of typhous fever. One man is affected with typhous fever, and his neighbours escape. The exciting cause of the fever is supposed to be something peculiar in the air. But his neighbours have been exposed to the same peculiarity, and are not affected with fever. We explain this by saying that his health was not previously good; that he was not in a state to resist the influence of the cause. This presumed disorder of his health was in this instance, then, the cause which predisposed him to the influence of the exciting cause of the fever. In the same way we see, of half a dozen persons simultaneously exposed to cold and moisture, one becomes affected with sore throat, one with pleurisy, and one with rheumatism; and the rest may continue well. The exciting cause was present to all, but a predisposing cause existed only in some, and was different in each of those in whom it did exist.

If we retain the term *proximate cause*, it signifies, in these cases, the pathological condition of the throat, the pleura, or the joints; but we think the term may be advantageously banished from medicine.

The chances and the characters of disease are always in proportion to the force of the exciting cause, and to the degree of the susceptibility to its operation. Of several persons suffering from

what is called determination of blood to the head, one may have vertigo, another pain; one may have a fit of epilepsy, and one die apoplectic. The difference in the effect may be occasioned by a difference in the power of the exciting cause, or in the violence of the determination; or, the determination being equally violent in all, the different effect may depend on the peculiar susceptibility of each.

There are certain cases in which disease appears to be produced simply by the application of an exciting cause, without the existence of a cause predisposing. There are others in which an exciting cause often seems to be wanting. These inconsistent phenomena, however, are to be ascribed to our imperfect knowledge of some of the causes. A violent burn, a wound, or other accident, will produce inflammation of various tissues, with no other predisposing cause than the nature of the human constitution. A child, in a particular condition of atmosphere, will become affected with whooping-cough or measles; and the predisposition is here also inherent in the constitution of the body. When the predisposition is removed, as in ordinary cases it is, by the occurrence of these disorders, the child may be exposed to the exciting cause, the peculiar condition of the air, with complete impunity. The cases in which disease seems to arise without an exciting cause, are chiefly those of morbid formations, in which such cause exists in the supervention of certain actions not yet understood.

**FORMS OF DISEASE.**—Diseases, however various or complicated, or whatever are their terminations, admit of a division into two great primary classes; the first comprehending all *disorders of function*; the second all *morbid products*.

**Disorders of Function.**—The view taken of this class by the general pathologist is one which is continually enlarging with the progressive improvement of physiology. Its leading features may be spoken of in connection with the two most important symptoms of the body, the vascular and the nervous. Nearly every disordered action which can be conceived to exist, must be intimately connected with some irregularity in one or both of these systems.

1. In the *vascular* system we observe, *a.* local determinations or local accumulations of blood, productive of an excess of supply, with excitement of the part supplied in excess; or congestion, with oppression of the part congested. *b.* Local defective supply of blood, producing or contributing to produce, defective secretions, defective energy, external discoloration, and a tendency to other disordered actions. Of these may be mentioned as examples, defective supply to the breasts or uterus in feeble women; to the hair in old or sickly persons; to the brain and other organs in those convalescent from fever; and to the feet in diseased or aged persons, with a tendency to mortification. *c.* General excess of blood, or plethora; the results of which are very various; *e.g.* increase of natural secretions, exhalations, and the vigour of different functions; irregular actions; excessive growths; and, perhaps, other morbid formations. *d.* General defect of blood, or anæmia. *e.* The state of the blood-vessels in inflammation, whether common or specific, as in croup, &c. *f.* The state

or actions of the blood-vessels in misplaced and new formations, including altered conditions of the blood contained in them.

2. In the *nervous* system we equally observe excess, defect, and irregularity of distribution. *a.* Local excess of nervous power; a state often accompanied with excessive sanguineous supply, but not invariably. To this excess of nervous power we cannot but attribute some of the instances of increased sensations and increased muscular actions in maniacal and hysterical persons. In the cases of increased secretions, increased absorption, increased nutrition, and increased evacuations; comprising the unusual flow of tears, or bile, or urine; the sudden disappearance of dropsical accumulations; hypertrophy of organs; diarrhoea, and excessive perspiration; a mixed explanation must be admitted: and in most of these circumstances, or perhaps in all except that of increased absorption, there appears to be a simultaneous excitement of the nerves and the blood-vessels. *b.* So, also, the general excess of nervous power, or general nervous excitement, is not often seen distinct from excitement of the vascular system. Either, first existing, seems to induce the other. The nervous excitement may, however, exist first, and therefore separately. *c.* The general defect of nervous power is shown in the weary and exhausted, and in some forms of incipient paralysis. It is observed in many other instances, but generally co-existing with defective power of the vascular system. *d.* Local defect of nervous power is seen in persons affected with tremors, chorea, and partial paralysis; in idiots and lunatics, whose intellectual actions are weak, impeded, or disordered, whilst their digestive powers are often unimpaired or even increased. It is observable also in the sick, the feeble, and the aged, and is one of the most ordinary precursors of death. The instances of deficient secretions, deficient nutrition, and deficient evacuations, are, as the reader will suppose after what has already been said, to be viewed generally as the consequences of a simultaneous defect in the nervous and vascular actions. If it be admitted that the action of the absorbents depends on the nerves, deficient absorption would in some instances appear to depend on defective nervous supply to the absorbent vessels. It is highly probable that some of the disorders of the function of respiration depend on deficient actions in the respiratory nerves. In some of the instances of chorea, as in tetanus, and in hydrophobic convulsions, the disorder of the nervous system probably consists of excess, or of irregularity, rather than of defect. *e.* There is, apparently, a morbid condition of the nerves in all inflammations, and evidently in some, as in gout. *f.* There are probably disordered nervous actions, in no degree yet understood, concerned in misplaced and in new formations, including altered states of the blood itself.

One very important example of general disordered action has been left out of this enumeration, namely, *fever*. Its place must depend on the yet undecided question of its actual nature. The vascular and the nervous depression, and the subsequent excitement of both the blood-vessels and nerves, are sufficiently evident. But not only is the order of these phenomena yet undetermined,

but their relation to a primary impairment of the vitality of the blood at least not disproved. For this reason we pass on to the *second* great class of diseases, or morbid products.

**Morbid Products.**—These may exist in the solid or in the fluid components of the body. They probably seldom arise from disorder of one of the great systems without coexisting disorder of the other. In their characters they vary exceedingly, as will be made apparent by the following, which is still an imperfect enumeration of them.

a. The effects of simple determination of blood, or local excess, which seems to be not only in many cases an increase of natural discharges, but alterations in their properties. These have not been very closely investigated. The sudden, profuse, and watery discharge from the mucous membrane of the nostrils incidental to some individuals from slight causes, and distinct from common coryza, affords an example of this class; and sudden evacuations from the skin, or bowels, may be also mentioned. The redundant growth, or hypertrophy of organs, demands, for one of its accompaniments, or rather one of its causes, this increased determination of sanguineous material; but such departures from the natural state should perhaps be classed in another division (c). Active hemorrhages are another consequence of increased determination to particular parts.

b. The effects of inflammation;—serum, lymph, false membranes on serous surfaces, pus, thickenings of parts by intestinal depositions, gouty concretions, the diphtheritic formations on mucous membranes, as in croup, and in inflammation of the mucous lining of the intestines or the vagina; and the peculiar matter found in scrofulous glands.

c. Natural secretions or formations misplaced;—bone in soft parts, as in the membranes of the brain, in the heart, in the blood-vessels; fat about the heart, or in the substance of the liver; misplaced fibrous tissue, cartilage, cellular tissue, hair, nails, serous tissue (in certain tumours, *Bichat*), mucous tissue (in fistulæ, *Hunter*), enamel (in some diseases of the joints), synovial membrane (in false articulations), arteries, veins, and nerves (in some tumours). These misplaced productions are often imperfect. They do not necessarily endanger life, although they are often inconvenient, and sometimes dangerous, in consequence of their situation or the size to which they attain. In certain cases they are formed for the preservation of life; as in the case of the fibrous masses formed in aneurism, and of the cysts or boundaries of abscesses.

d. Altered secretions;—soft or fragile bone; acrid bile; the disorders of the urine accompanying calculous formations.

e. New formations, not the product of inflammation. In this class may be placed the various tumours—common, adipose, pancreatic, mammary, and tuberculated sarcoma; and encysted and osseous tumours; all of which are of a local character, and many of which coexist in some instances, as in certain enlargements of the ovary. To these must be added the more serious formations connected with some taint or fault in the constitution; as scirrhus, tubercles, scrofulous enlargements, encephaloid tumours or fungus hæmatodes, and melanosis. Hydatids, worms, diseased

exhalations, (as ascites, in disorder of the liver,\*) and changes in the nature of the blood itself, belong also to this class; and also the calcareous productions found in the lungs and bronchial glands. Many of the products under this head are dangerous to life. Reacting on the imperfect constitution in which they have originated, they occasion fever, various functional irregularities, emaciation, and death. They are frequently accompanied by inflammation, the supervention of which appears to accelerate their progress; but in their origin, in their first symptoms, and in the wide difference existing between them and the ordinary products of any of the forms of inflammation which are the results of accidents, or can be excited by artificial means, we have so many reasons for ascribing them to processes quite distinct from the inflammatory process.

**THEORIES OF DISEASE.**—These observations bring us immediately to the great question of the *origin* of these important departures from health; not only as regards the new products of disease, but the misplacements and excess and depravation of some of the natural products; the solution of which cannot precede the determination of some unsettled questions in physiology. When the laws and processes of secretion are clearly demonstrated, the next step will be an accurate knowledge of the diseased actions in which morbid products originate.

The alterations occurring in the fluid parts of the body, but particularly in the blood, which once attracted so much attention as to be the general basis of a pathological system, have recently, after experiencing the capricious neglect to which many doctrines containing much truth have at different periods been subjected, again drawn towards them the anxious attention of philosophical physicians. (See the article *BLOOD*.) The vital and, as it were, independent properties of the blood are no longer overlooked, and the important office performed by this fluid in relation to the secretions, an office extending beyond the mere supply of a material for their formation, directs the inquiries of the pathologist towards those intimate changes which, taking place within the arteries, or even in organs contributing to the unexplained function of the hæmatosis, are the real causes of the singular and abnormal products presented by various diseases. Thus we may in the present time perceive the dawn of a new humoral pathology, more correct, and at the same time less exclusive, than that which from the age of Hippocrates down to nearly the end of the seventeenth century prevailed throughout all the schools and doctrines of medicine. Without reverting to the dreams of the mathematical physicians, the doctrine which ascribed so many of the phenomena of disease to the *moving powers*, will not be discarded; and even the first changes traceable in the blood itself may be acknowledged to depend upon irregularities in actions of which the very existence is yet in the utmost degree obscure.

When it is considered that five-sixths of the materials of the body are fluid; that all the materials even of the solid parts primarily exist in a

\* In a case of hypertrophy of the heart, the patient's perspiration tinged his linen, and the lining of his hat of a red colour.

fluid state, and are again reduced to fluidity before their ultimate removal; it is quite in vain to deny the importance of paying attention to diseased states of the fluids. But physiology teaches us that the formation of the fluids depends, no less than that of the solids, on certain preceding actions, and that the disturbance of these actions is often known to be, and may probably always be, antecedent to the diseased condition of the fluid parts.

In some circumstances the blood is seen to be so suddenly deprived of its vitality, that the primary impairment of that vitality in other cases where there is a long series of morbid phenomena, becomes exceedingly probable. When death is occasioned by lightning, by a violent blow, or by the poison of a rattle-snake, and sometimes even by the unknown poison which produces a sudden and violent attack of fever, in which the patient dies without re-action; the most palpable disorder is effected in the blood itself, which is found to be deprived of its natural and vital properties. The change in these cases is so instantaneous, that even if we admit an antecedent change in the nervous actions, we admit what we are at least unable to demonstrate. Recent observations have made it highly probable that in a severe attack of the spasmodic cholera, the serum and some of the saline constituents of the blood are forcibly separated from the red globules.

In the instance of melanosis, some pathologists have considered the black formation to be a deposit from the blood, which has previously undergone some peculiar change. The growth of polypi may perhaps be attributed to some change by which the fibrine is separated from the blood.

In other cases, where the duration of less violent phenomena is more prolonged, as in the case of eruptive fevers, we have every proof of the action of the first cause of the disease upon the fluids. In the small-pox we are enabled to communicate the disease directly through the blood to the whole system.

The great respectability of the authorities which might be ranged on one hand as supporters of the doctrine of fever being produced by an atmospheric poison acting upon the blood;—and, on the other hand, as supporters of the doctrine which, admitting the sanguineous changes and their consequences, assert the primary action of the febrile poison on the nervous system;—very forcibly shows the difficulty of determining the question by observation, and in the present state of physiology, of unravelling the intricate implications of the nervous and vascular systems in the performance of healthy, and consequently of diseased actions. Any one acquainted with the present state of medical science, and possessed of some share of ingenuity, might construct a plausible theory by attaching himself to either one or the other of these great systems. The more palpable indications of disorder, although that disorder is often but re-action, would probably cause the number of those espousing the *vascular* theory to be the most considerable; whilst the undefined limits of nervous influence would give to the *nervous* theory all the advantages to be derived from bold and unrestrained conjecture. In the mean time, a true and permanent doctrine would

still be eventually found to lie between these extremes, and to be founded on the triple basis of cotemporaneous disorders of both the great systems, and on the occasional primary affection of either one or the other.

At no period since the first cultivation of medicine have physicians ever been so free from any predominant and absorbing theory of diseases as at the present time. So great, indeed, has been the zeal with which facts and cases have been collected, that the age is somewhat open to the reproach of having reasoned upon them too little. Yet, when it is considered how indispensable to a correct system of pathology is a previous enlargement of certain parts of physiological science, it ought to be matter of praise rather than of censure that the physicians of the present day so much abstain from premature conclusions. When the physiologist can explain the formation of the several secretions from the blood, and the workings of the fine apparatus by which these formations are effected, and new parts formed, while old parts are carried away;—when the relative dependences of the nervous and the vascular systems are determined, and the chemistry of the animal fluids in disease as well known as is that of their normal state, then, and then only, will the doctrine of the intimate nature of diseases become exact.

One or two of the general theories of disease, however, which have been prevalent since the commencement even of the present century, may be alluded to. A great majority of the pathologists of this country, who ascribe disease to disordered actions, for a time adopted the views of the late Dr. Parry, of Bath. He was a physician of great talents and great industry. Amidst the fatigues of a large practice, and many interruptions from ill health, he found time to make observations upon almost every form in which disease presents itself; and he proceeded a considerable way towards forming these observations into a great system. Perceiving the error of the older practitioners, who, in their attention to nervous phenomena, overlooked their frequent dependence on vascular disturbance, he rejected, most certainly in terms too positive and unqualified, all idea of a nervous theory, and looked for the origin of almost all diseases to some irregularity in the powers which move the blood. This theory was actually applicable to so many and such severe affections, not a few of which had been previously misunderstood and very erroneously treated in practice,—and it was moreover so specious and so convenient, that it promised fair at one time to be universally adopted. There were few forms of disorder in which it seemed very difficult to admit, either that the impetus of the blood in the organs chiefly affected was morbidly increased, or, without general disturbance of the circulation, the tonicity of the arteries proceeding to such organs was diminished, their elasticity preponderant, and their resistance to the usual momentum of the current of blood morbidly decreased. In either of these cases, one of which was often capable of demonstration, whilst the other always admitted of supposition, and not unfrequently existed, the morbid phenomena present in each case were ascribed to undue determination of blood.

Of many diseases the first palpable phenomena are affections of the vascular system. But that there are morbid actions in which, even when visibly increased or disordered vascular action is present, it is but an accompaniment, however inconvenient and even hurtful, is sufficiently evident. The mere disorder in the circulation will not account for the various morbid processes incidental to the scrofulous constitution, or for many of the affections of the digestive, respiratory, mental, and other functions. With all our respect for Dr. Parry, and there are few authors for whom we entertain a respect more sincere, it is impossible to go along with him, when, as if to show his theory in the most advantageous point of view imaginable, he speaks of "that increased determination of blood to the lower extremities which constitutes gout." (Elements of Pathology and Therapeutics, cccclvi.)

We cannot, in short, possibly exclude the idea of a peculiar constitution of nervous substance, or modification of nervous action, although such constitution and modification are only perceived by certain effects for which no other satisfactory cause can be assigned. If such a pathology be still imperfect, it is only so because physiology is circumscribed. When the nature of that nervous power or influence is understood, which in one part of the nervous substance effects motions in other structures, in another part permits sensation, in another volition, in another the internal sense which governs some of the most important animal processes, and in another all that we call intelligence, then may the pathologist presume to hold a bolder language, for he will then advance to facts with which he is at present quite unfurnished and unaided.

In the mean time, the pathological connection between the two great systems, of which illustrations have been already given, are even now not neglected in practice. The relief of some nervous disorders is attempted, and often effected, by means acting primarily on the vascular; as in the case of hysteria, in which venesection is so frequently more serviceable than any of the means which are considered to act immediately on the nerves. There are cases of inflammatory disorder in which the best auxiliaries of blood-letting are sedatives, which seem simultaneously to allay nervous and vascular irritation. Attempts are alternately made to check the progress of morbid formations, as of scirrhus, by lessening the supply of blood to the part affected, and by soothing the nervous system. In phthisis pulmonalis, we endeavour to decrease the general momentum of the blood, or the irritability of the heart and arteries, without repeatedly lessening the general quantity of the blood; and the means employed, as, for instance, the digitalis or the hydrocyanic acid, seem to act on the whole vascular system by first acting on the whole nervous system. These are so many exemplifications of a liberal and philosophical theory of diseases, which, without being formally avowed, appears to us to have been acted upon for many years past, in this country, in a variety of disorders. It is not unpleasing to observe with how little pomp such a system has gradually spread its rational influence over British practice; its unpretending character arising ap-

parently from its being little more than a reflection of undeniable facts.

The strong disposition of the human mind to rest and generalize after the fatigue of acquiring or observing a limited number of facts, has even divided into at least two sects those who ascribe disease to disordered actions; and these, adopting a nervous or a vascular theory, are only distinguished by the particular position they have selected, by the particular facts or phenomena on which they take their stand, and which they believe in every case of disease to precede all the rest. A few, and but a few, of the distinguished teachers on the continent yet cling to the assertion that all disordered actions must be preceded by organic or structural change; an assertion implying too complete a reversal of the order of observable phenomena to require any discussion. But a much larger sect is composed of those who ascribe all morbid phenomena, all disease, all structural change or new formation, all disordered action, to some shade or other of inflammation; rather, it is to be apprehended, from a misapplication of language, and the too licentious extension of the term inflammation, than from a real and unqualified proselytism to so sweeping and unphilosophical a generalization. Another sect, the followers of M. Broussais, whose talents, unbounded confidence in himself, and vehement eloquence, have attracted some and scared others to swell the number of his disciples, acknowledge no other origin of the most remote diseases than disordered action, irritation, or sub-inflammation of the mucous lining of the intestinal canal; a plausible doctrine, resting on numerous facts, and largely intermingled with truth, but which becomes useless or unsafe when it is made universal.

But whilst almost all the schools of Europe, and we may add of America, have been distinguished by a calm and philosophical spirit, averse to mere hypothesis, and little addicted to implicit adoption of the tenets of any single master—*nul-lius addictus jurare in verba magistri*,—a sect has arisen in Germany, chiefly consisting of men whose enthusiasm far outruns their powers either of observation or of reasoning, and embodied under the appellation of Homœopathists. To omit all notice of this sect might be considered improper in so general an article as the present; yet to speak of their opinions and practice without departing from the ordinary style of medical discussion is somewhat difficult.

Not without the credit of having pointed out some unnoticed circumstances connected with the administration and effects of medicines, and even deserving of some praise for having enforced a few salutary maxims of diet and of regimen; the founder of this sect, Dr. Samuel Hahnemann, surpasses all the heads of all the sects that ever flourished, or that have been forgotten, in the boldness of his assertions, the careless extravagance of his deductions, and the scorn with which he regards all whom he fails to persuade.

According to the doctrine thus presented to the hitherto deluded followers of physic, the art of curing diseases consists of the employment of medicines in each case, which, in a person in good health, would produce a similar disease. There is, we think, an ancient proverb which comprehend-

the grand principle of homoöpathie, "what will cause a fever will cure a fever;" a doctrine which appears, at first sight, hardly more reasonable than if one were to say, what will make a man drunk will make a man sober; or, what will break a man's leg will set it. Although, as is the case with any assumed general principle, a few specious facts may be quoted in support of it, or its truth may be admitted in a very limited number of instances, no one who reflects on the methods now, by universal consent, adopted in the treatment of the large and important classes of febrile and acute inflammatory disorders, can fail to perceive that a principle from which these and all surgical diseases must be excluded, has no claim to be looked upon as general. It can be no matter of surprise that a mind which can calmly entertain such a delusion, should believe that medicines daily used with the effects desired in using them would be more useful, nay, more energetic, if employed in doses a million, a trillion, or a decillion times more minute. Even of this extraordinary diminution of dose, and of its good effects, some examples may be adduced, which all must admit—that of mineral waters, for instance, although we are not sure that Hahnemann has availed himself of it. But, in this case, small doses are useful where larger doses of the ingredients of the water would be positively hurtful; and there is something, too, in the chemistry of nature not yet perfectly imitated by art. In many of the cases appealed to by the homoöpathist, (mercury, henbane, &c. being employed,) larger doses are given daily and with the best consequences, and in the same description of cases in which the followers of Hahnemann would divide a single dose into portions sufficiently numerous for all the patients in all the hospitals in the world. Still the narrow principle is again admitted, as universal, undeniable, and now first revealed to mankind. Precisely the same kind of reasoning pervades the homoöpathic doctrine of *chronic* diseases, *all* of which are ascribed to syphilitic taints or to some form of cutaneous disorder: thus adding another to a thousand previous instances, that in the circle of diseased actions any separate portion may be fixed on as the universal beginning by those whose defective sight is confined to that portion.

The reception of such doctrines, even by a few individuals, in any country where the reasoning powers are not utterly neglected, can but be regarded, to use an expression which the late Dr. James Gregory used to apply to such follies, as a pitiable proof of the ignorance and credulity of mankind. No one will think such censure unjustly applied to Homoöpathists, if he recollects, that without disputing concerning the examples which they bring to support their great principle of curing by resemblances, its absolute admission would dictate that ardent spirits should be given in phrenitis, in gastritis, and in cystitis; opium in lethargy and coma; turpentine in irritable states of the urethra, and aloes in painful hemorrhoids; and that the only defence to be made against the accusation of merciless and even fatal practice in such cases, rests on the tenfold greater, although less dangerous, folly of giving the ardent spirits in doses of five hundred parts of a drop,

and the turpentine and aloes in doses of the millionth part of a grain.

RELATIONS AND CONVERSIONS OF DISEASES. —Dismissing the subject of general theories of disease, it belongs to the general view of the laws which govern morbid actions, to notice the singular relations which exist between affections of different parts of the body, and also the conversions of diseases which are sometimes found to occur.

These may be viewed in connection with the vascular or the nervous system. The relation and conversion of diseases dependent on a state of plethora are so commonly observed as to be known to all practitioners. Such a condition not only disposes to all inflammatory disorders, but may induce the especial embarrassment of any single organ without inflammation; as, in the lungs, asthma or pulmonary apoplexy; in the brain, lethargy or cerebral apoplexy. Combined with a predisposition or susceptibility of the nervous system, it may concur to the production of gout or of mania.

As regards the relation of affections of the nervous system, we see whole families—every member exhibiting the family susceptibility, but each in a different manner, either from different portions of the nervous system in each being inadequate to healthy actions, or peculiarly affected by the circulating system. Eccentricity, excessive shyness or timidity leading to seclusion, chorea, epilepsy, amaurosis, mania, and other nervous affections, are very commonly observed thus associated by the bonds of relationship, giving as distinct a character to large families as the most peculiar external features of resemblance transmitted by inheritance.

New directions given to certain portions of the blood, together, probably, with a transference of morbid actions in the nerves, may cause not only the conversion of gout to mania, already mentioned, but of erysipelas of the scalp to phrenitis, or of erysipelas of the trunk to sub-inflammation of the intestinal coat with diarrhoea. The sudden repulsion of some of the disorders of the scalp in children, as of porrigo, is not unfrequently followed by meningitis. The sudden recession of the cutaneous efflorescence and inflammation in rubella, scarlatina, or variola, is commonly followed by inflammation of the lungs, or the bowels, or the brain. The supervention of an affection of a new organ, or the subsidence of a similar disorder of an organ primarily affected, is usually termed *metastasis*; among the most familiar examples which may be mentioned, is that of rheumatism, in which the articular affection, when it suddenly ceases, is not unfrequently followed by inflammation of the pericardium, and even of the heart itself.

Irritations of the nervous system, of which the actual nature is very obscure, but the effects are very serious, may now and then be observed to succeed each other either by natural conversion, or in consequence of means employed for the cure of that which first existed. The most striking case of this kind which we ourselves have witnessed was that of a lady, who had been for several years affected with melancholia without any discoverable cause. When all the resources

of ordinary means and medicine had been unavailingly exhausted, she was persuaded to try the prescriptions of an irregular practitioner. By his advice she persevered for some time in the use of the corrosive sublimate, together with large doses of the sulphuric acid. The mental depression gave way whilst she was taking these medicines, somewhat, as may be supposed, to the discomfiture of those who had vainly attempted to produce the same good effect. In a very short time the same patient began to complain of pain referred to the back and loins, of a burning character, at first occasional and not very severe, but which gradually became heightened to the extreme of human agony. Medical and surgical skill were fruitlessly exerted even to give temporary relief, and no means seemed for a moment to suspend the malady, or to give the faintest hope even that the principle of transition or conversion could be brought into operation for the patient's benefit. Her sufferings were unintermitting, except during short and broken intervals of sleep, for nearly two years: the lower extremities became powerless, then contracted, then inflamed by contact; and these complicated afflictions only ended in death.

The most singular transitions of nervous irritation are exhibited in hysteria, in the course of which the most severe inflammatory affections are sometimes simulated in succession.

The inconveniences following the removal or cure of chronic diseases are often such as to make the propriety of endeavouring to put an end to them somewhat doubtful. After the cure of a chronic diarrhœa by metallic astringents, we have noticed the re-appearance of scrofulous ulceration of the skin; and in a case in which this had occurred, and the ulceration was healed by a desperate quack, symptoms indicative of pulmonary tubercles immediately appeared, and death ensued. The same phenomena have often been known to follow measures calculated to repel enlargements of the cervical glands. We have many times observed the supervention of various inconveniences on the disappearance of chronic or habitual coughs. The cessation of gout, or the suspension of hemorrhoids, has often been followed by epilepsy or by asthma. These accidents, of which a long list might be given, prompt a very important indication to be observed in the treatment of all such affections, which will be dwelt upon in the article MEDICINE, PRACTICAL, PRINCIPLES OF.

Occasionally there is a translation of diseased exhalations or effusions. Anasarca will subside, and œdema of the lungs will follow. Hydrothorax or ascites are sometimes much relieved by dropsical swellings occurring in the extremities. General dropsy has come on after the cure of epidrosis, both affections seeming frequently to be meant for the relief of plethora.

Some affections are suspended during pregnancy, apparently in consequence of a converted determination from the part disordered to the uterus. The instance of phthisis has frequently been observed; and we have noticed remarkable examples of it in obstinate and extensive psoriasis. It is curious that the determination to the mammæ during lactation does not prolong the benefit; a fact which common observation confirms as regards consumption, and which we have equally noticed

in the example of cutaneous disease. The object of the law of nature here exemplified seems to be the preservation of the species, which after parturition may be vicariously performed.

#### MODIFICATION OF DISEASE BY TEMPERAMENT.

— Other modifications of disease arise from what are called *temperaments*: they modify the predisposition to receive disease from the several causes which have been mentioned; and they modify the course of disease when it is excited by any cause. The term temperament, however, founded on an ancient doctrine of four humours supposed to temper each other, but long employed without reference to the theory in which it arose, and often with a vague and unsettled signification, is among the inconveniences of medical nomenclature, which so many have prided themselves on deforming by new additions of barbaric jargon, and so few have attempted to purify and improve. The *sanguine* temperament (indicative of the predominance of the sanguineous system), the *choleric* (or bilious), the *phlegmatic* (or pituitous), and the *melancholic* (or atrabilious), are designations which, however frequently and familiarly employed, convey little precise meaning, and that little not always correct. The sanguine temperament is supposed to be characterized by a full habit, a soft skin, a ruddy complexion, red or auburn hair (the *flavus* of the Romans), and what the Scotch still call yellow-haired), a frequent pulse, large veins, and vivid sensations. The melancholic, on the contrary, is described as existing in a firmer frame, and thinner, with a dark skin, black hair, and a slow circulation: the nervous system is less easily moved; the disposition is grave and meditative (*meditabundus*, Gregory, in *Conspect.* cap. xxiii.), and the affections are fervent and steady. Intermediate between these is the choleric. But the phlegmatic differs from all in the laxity of the skin, the paleness of the face, the lighter colour of the hair, and the greater sluggishness of the faculties of the mind.

It is unquestionable that this ancient division must have been the product of extensive and delicate observation. It is even possible that when the varieties of men were less mixed, the temperaments, some of which continue the characteristics of nations, were less blended. At present, all attempts to limit the inexhaustible varieties of temperament, compounded, it may be, of so few and such simple elements, is as unsuccessful as to comprehend within the bounds of a few descriptions all the variety produced by the different associations of the few features of the human face. However interesting, therefore, a recollection of the temperaments may be to him who speculates on the varieties of human character, it now affords little help to the practitioner of medicine, and a consideration of their divisions may advantageously give place to one which has the recommendation of being at once more simple, not less comprehensive, and more easily admitting every diversity.

There is an evident difference in the susceptibility of different individuals to external and internal, to bodily and mental impressions; and this susceptibility, to the expression of which we would in medical language limit the word temperament may be, and doubtless sometimes is, uniform

throughout the whole individual frame of body and mind. But it is so often irregularly disturbed, and so often variously limited in different individuals, so liable also to transitory and permanent increase or diminution from various accidental causes, that it requires, for any useful pathological or therapeutic end, to be regarded with little or no reference to an arbitrary division admitting only of complete individual varieties. From the original or constitutional excess or defect of susceptibility to one or more, or all the impressions which the mental and bodily frame is intended to feel, arise various diseases, and the diseases affect, for the same reason, a particular course. The susceptibility may be so increased, that common light, common air, common sounds, common food, common occurrences, cannot be tolerated: it may be so diminished that these circumstances do not affect the senses on which they are intended to act. But the susceptibility may be partial; increased at one time, diminished at another—increased in one organ, and not in others; diminished in some organs, and in others increased.

To this kind of susceptibility the practitioner is required to pay much attention, in order to discover the tendency in his patients to particular forms of disease, and the consequent propriety of pursuing particular methods of cure. The occurrence of disease in any organ commonly, for a time, increases or diminishes its susceptibility to ordinary impressions. Thus, after fever, the brain and the intestinal canal occasionally remain for some time irritable and intolerant of all impressions, and in other cases for a long time inert and torpid. The disease of some organs induces or is connected with peculiar states of susceptibility in others. During the progress of tubercles in the lungs, the irritability of the heart is very conspicuous, and that of the bowels is not unfrequently fatal. In morbid states of the brain the stomach is sometimes irritable, and vomiting is a symptom; and sometimes in a state so completely opposite that powerful emetics will not rouse it, and food is obstinately refused. In the same individual we may see the mind excited, or exhibiting, if we revert to the old terms, the peculiarities of the sanguine temperament, and the stomach, bowels, and skin decidedly phlegmatic; and to such cases no general term can correctly be applied. All these varieties of susceptibility undergo modification by climate, by diet, by excessive evacuations, by the neglect of exercise, by exclusion from pure air, by mistaken habits as regards clothing, and by other causes of which the importance is fully shown in the article EDUCATION, PHYSICAL, to which the reader is referred for many particulars which could not properly be here introduced. Modifications, both as respects the whole body and particular parts, are effected by age, and are noticed in the article under that head already referred to.

Generally speaking, there exists in women a greater degree of susceptibility to impressions than in men; and this is very often observed in that degree of excess which constitutes what Dr. Cullen called *morbidity*, and which is the affliction of the greater number of those who are termed nervous patients. These are the individuals who feel all the impressions of sense with almost pain-

ful acuteness: they long retain, and vividly recall, the impressions of music and of painting, except when new objects excite them, and therefore longest in the dark; and they are prone to hysterical affections, as various as the sensations and actions can be which may be associated with morbid conditions of all the various parts of the nervous system. (See HYSTERIA.) The importance of being acquainted with the modifications of disease in a temperament of this kind is very great indeed. Such patients are not only more readily affected by disease, but by remedies, than other patients. Soon reduced to apparent weakness, the same facility of being acted upon by various stimuli occasions their recoveries to be often equally sudden, and to the inexperienced practitioner surprising. Both the prognosis and the treatment must be regulated by these circumstances. Violent medicines will do the patient harm and him discredit. The pale, languid, feverish, irritable, complaining patient of to-day may before to-morrow be converted, by the unexpected visit of a friend, into a patient no longer submissive to physic, or mindful of slight ailments, but anxious to return to all the amusements of a dissipated life. In proportion as there is in the male sex an approach to this mutable susceptibility, the practitioner must expect the same results, and observe the same caution.

VIS MEDICATRIX.—The signification and value of the medicinal symptoms and signs of diseases are treated of in the articles PROGNOSIS and SYMPTOMATOLOGY. There is, however, one view of symptoms in general which especially belongs to the general subject of disease; namely, their frequent indication of that power in the system to which has been given the appellation of a *vis medicatrix nature*. This curative power or property, although the idea of it may have been pushed needlessly far, and rendered somewhat too material, is an undoubtedly existing property of the living animal body. It is this which Van Helmont personified as the archæus, or grand regulator, whose throne was the stomach. It is what Wepfer called the president of the nervous system: and we do not see that Stahl went beyond them when he referred the government of the body “directly and entirely to the rational soul,” diffused, however, over the whole body.\*

The truth is, that we have daily proofs of there being a power in the constitution to repair injuries and restore lost parts; and that several actions which we call disease are instituted to get rid of the causes producing them. Nor is there any necessary extravagance in the supposition that the possible intention of all may be so. The law may, perhaps, be said to be analogous with, or conformable to, the law of which natural philosophers have gained a knowledge by induction from various phenomena; that all *action* is followed by *reaction*, equal to, but different from, the primary action.

If a bone is broken, if a muscle or tendon, or even a nerve is divided, the divided ends are reunited. If a portion of substance, as of the skin and cellular membrane and muscle, is lost, or cut

\* See Hoffman, Commentarius de differentia inter Hoffmanni doctrinam medico-mechanicam et G. E. Stahl medico-organicam.

out, the deficiency is repaired, and the cavity built up by granulations from the bottom, and at last covered in by new skin. If a part removed is without much delay re-applied—a tooth, the tip of the ear, a finger, a part of the nose—it becomes firmly united in its original situation. So anxious, if we may so speak, is nature to preserve the life she has given, that wounds of the most important organs will cicatrise; wounds of the lungs, of the heart, of the intestines, of the bladder, of the uterus, even of the brain.

Dr. Parry enumerates among salutary processes, re-action, shivering, convulsions, bodily exercise, tears, sighing, gout, dyspepsia, formication, vertigo, coruscations, fever, loss of appetite, and wasting. The propriety of including some of these may appear questionable; but illustrations of the salutary effects of the greater number will so readily present themselves to those familiar with pathological phenomena as to require no further observation. Many cases of conversion of disease are, of course, to be referred to the same head.\* Viewing the principle in its widest extent, it may be said to be first exemplified in the convulsions of infancy; and it is exhibited for the last time, and ineffectually, in the convulsions so often preceding death.

There is a kind of consolation, not unattended with a hope of the final extension of medicine far beyond its present powers, to be derived from observing that even diseases of a most fatal character evince a conformity, as it were, to the same great curative and preservative law. The whole series of changes in the tubercle are but so many efforts to dislodge and eliminate it from the lungs; the process is attended with irritation, and by long continuance, or rather by constant repetition, it generally ends in death. A similar process prevails in cancer, and is sometimes, although rarely, more happily effected. Calculi in the bladder occasionally become enveloped in pouches of the lining membrane, and irritate the patient no more; and sometimes escape by ulceration into the rectum or vagina, or through the abdominal integuments.

There can be no difficulty in admitting these indications of the *vis medicatrix naturæ*, without referring them to anything more than an internal sense, which the preservation of existence did not require to be of the same nature as what are called the external senses. It would be hardly necessary to allude to the more material character given to this power, if the physicians who were most disposed to invest it with personal properties and dignity, had not, as a natural consequence, become too scrupulous about opposing it, even to the extent of curing all diseases by what the French have called *expectation*.

The proper advantage of acknowledging such a power is, that it prevents indiscriminate and officious meddling—that medicina *perturbatrix* which incessantly contradicts even the best efforts towards a natural cure. In the modern practice of medicine and surgery, the *vis medicatrix naturæ* is seldom disregarded; but its suggestions are not followed without discretion. Seeing the intention of its working, it is yet often seen by the

practitioner to work in a dangerous manner, and too much by a general rule; sometimes too abruptly, and sometimes after too lingering a manner. The object of art is to adapt the rule to particular instances; and the greatest wisdom of the practitioner is shown in determining when to wait upon nature, when to rouse her to exertion, when to moderate those exertions, and when to put an absolute stop to them.

When a bone is broken, the body being previously in full health, the *vis medicatrix naturæ* is soon in full activity; the whole restorative force is called out. The vascularity, the heat, the vitality of the surrounding parts is increased; and inflammation ensues. But it is often necessary to moderate this zeal and haste of nature; to lessen the superfluous excitement, leaving only that degree of it without which the repair cannot proceed. Among savages the natural power of healing is so perfectly exercised, that it is said the most frightful wounds will heal without surgical aid. On the other hand, a patient of infirm constitution or disordered health becomes subject to some local congestion; or some accidental and trifling injury brings a part of the integuments into a state of chronic and inactive disease; and the *vis medicatrix naturæ* is not exerted until the obstacle to its exertion, the disordered state, perhaps, of the digestive organs, is removed by alterative medicines: but that done, and a wound or abrasion, which had remained stationary for weeks, instantly puts on a new character; secretory and absorbent processes are at once commenced, and the cure is soon completed.

We see, too, in the case of a patient alarmingly lowered by an attack of fever, the nervous energy sunk, the power of the heart diminished, the digestive function almost annihilated, the respiration laborious and feeble. Nature, unassisted, will undoubtedly try to make this patient rally: but if the trial is successful, it can only be so in the course of many weeks, perhaps many months; and the body and the mind will long continue to suffer, or perhaps never wholly recover. Often, after a succession of attempts, the patient sinks at last. But we know that by stimulants and tonics judiciously administered, we can rouse the powers of digestion, and re-animate the whole frame, in less than half the time and with less than half the danger.

Whilst, however, we seriously consider the design of nature in any malady,—whether she is working, and how she is working, and how the machinery will endure the process she has set up—we should still, having to treat diseases as they occur in civilized life, never trust entirely to the *vis medicatrix naturæ*, except in the case of the most trifling injuries, where a process of very small extent is all that is required for the cure.

The natural powers of healing and recovery are in many cases strongly influenced by peculiar mental states. The same emotions and passions which redden or blanch the cheek, which affect the cutaneous and renal functions, or those of the stomach and bowels, can also promote or retard the activity of the *vis medicatrix naturæ*. Confidence of recovery often conduces to recovery; and extreme despondency concerning the tendency of a disease sometimes leads to a fatal result. This

\* See Parry, Elements of Pathology and Therapeutics, vol. i. Par. DCCCLIII to DCCCLXVI. Second edition, 1825.

is very conspicuous in some affections, as in fevers; and has often been asserted to prevail in malignant disorders, particularly in cancer: and some practitioners are consequently inclined to place implicit reliance on the prognostics in which their patients are disposed to indulge. But the example of phthisis, which is in that respect not singular among chronic disorders, may serve to show that confidence may be even a part of the disease, arising from a morbid condition of the sensorium: and we have attended patients in lingering forms of fever, which ended happily, yet throughout the whole course of which it was impossible to excite a ray of hope in the mind of the patient. In some cases the cessation of the fever induces a deep but temporary despondency of recovery. Even with these exceptions, the influence of the mind over disease should never be overlooked by the practitioner; nor should he forget to inculcate that this influence of the mind, like all the mental actions, may by firm endeavours be to a great extent subjected to the will.

**ACUTE AND CHRONIC DISEASES.**—The different period required by different disorders, unassisted by medicine, for the production of a natural cure, or, in fatal cases, for the destruction of life, has long been the occasion of a general division of diseases into *acute* and *chronic*. Acute diseases are commonly attended with severe and obvious symptoms; whilst chronic disorders are usually less marked, and attended with less suffering. To these distinctions there are, however, exceptions. Diseases of short duration, and in their effects destructive, are sometimes attended with few symptoms of the mischief they are effecting in the brain, in the lungs, or in the intestines; and diseases slow in their progress are often accompanied with sufferings of a very severe kind.

In acute disorders there is, except in rare instances, warning sufficient to guide the practitioner; but in chronic diseases the most extensive injury sometimes proceeds undiscovered until the discovery is useless. Acute inflammation, for instance, can seldom be overlooked; but chronic inflammation is frequently unnoticed until some of its worst effects on structure have been wrought by long continuance. It is no less essential to the physicians than to the surgeon to be especially mindful, in all obstinate maladies, of the possibility of serious disorder.

**PERIODICITY AND CRISES OF DISEASE.**—But there are also diseases, acute as regards their severity, and chronic as regards their duration, which are what is called *remittent* and *intermittent*. The symptoms arise and decline in a certain series and in a certain time; then disappear, and after a certain interval are renewed. The class of fevers remarkably exhibits all the peculiarities of remission and intermission; and these will be described under the head of **FEVER**. In this general view it may be sufficient to mention, that in our common continued fevers there is generally once, and sometimes twice, in the space of twenty-four hours, an observable remission or marked alleviation of the febrile symptoms. It is, however, in many cases not very striking; and it is always less striking in this country than in those fevers of warmer climates to which the observers have

agreed to give the name of remittents. In one class of fevers, sufficiently familiar to the practitioners of marshy countries, the remission is so marked and of such continuance as to be denominated an *intermission*. Each paroxysm of an intermitting fever or ague has a precise beginning, middle, and end, with an unquestionable cessation for a time, after which a new paroxysm is commenced. The intermission is never of less length than some hours; it is often twenty-four, and not unfrequently forty-eight.

Not, however, in fevers alone have these well-known but unexplained circumstances of intermission and remission been observed; diurnal remissions are distinguishable in every attack of inflammation. There are periods of the day or night in which the symptoms are less severe, and other periods in which there is an exacerbation. Even some inflammatory affections are intermittent, of which, perhaps, rheumatism is the most frequent example; although pleuritic and other inflammations have been described as assuming the same character.

An intermittent form of attack may very commonly be observed in many of the disorders usually called nervous or spasmodic; as in hysteria, epilepsy, and nervous asthma. Close observation will occasionally detect regularity in the attacks of epilepsy, where slight inquiry would not cause it to be suspected. We have sometimes found the alternate fits corresponding in point of time, and the paroxysms very nearly observing two distinct periods; so as to be somewhat analogous, only with much longer intermissions, to what is called a double tertian. The same intermission, more or less regular, and often with considerable intervals, prevails in a great number of cases of maniacal affection.

The intermissions in these instances appear sometimes to be associated with periodical changes, not appreciable except in their effects, in the nervous system itself. At other times there is a manifest periodical excitement of the vascular system; but whether a primary excitement or not, the progress of physiological and pathological knowledge will alone discover. The ancient cultivators of medicine attached considerable importance to the periodicity of inflammatory affections, even of the slightest kind; believing that whatever measures were employed, they would run a certain course, mitigated perhaps, but not prematurely brought to a termination. Both with respect to these and to the febrile disorders, certain days were believed more favourable to a termination of the malady than others, or even to its amelioration. These were called *critical* days. If the disorder did not begin to decline, or altogether decline, on one of those days, the hope of the practitioner was transferred to a future critical day, overlapping one or two days, and sometimes a greater number. Unfavourable changes were alleged to occur on the same days in bad cases. For a belief sanctioned by the acute observation of the Greeks, and more or less cherished by almost every sect up to the present day, it must at least be said that there must be some strong foundation. Yet on few points are modern authorities more at variance; some retaining the old faith pure and unmixed, some admitting it with reservations; and some

regarding it as a venerable but a groundless prejudice. We are not afraid to confess that our individual observation inclines us to rank among the believers; although at the same time we acknowledge the insufficiency of individual observation on a question of this nature.

There is some analogy between these periodic movements of disease, and the periodical performance of certain of the healthy functions, although, as regards several of the latter, the effect is commonly ascribed to habit. The desire for food, however, and that for sleep, which may be looked upon as indications of an approach to a state of exhaustion in some part of the system, are found to recur within a certain period in all; whilst in the instance of the uterine functions in the female, and in the frequent examples of inconveniences resulting from a plethoric state of the blood-vessels, there is a certain effect produced within a given and exact time, and with which habit can have nothing to do. Again, in almost all slight but not very transient disorders, there is an alternation of excitement and depression, "a good day and a bad day;" and, during convalescence, particularly from fever, we have often noticed the great distinctness of this intermittent or periodical character.

As from the earliest cultivation of medicine it was observed that some peculiar circumstance or state of the body accompanied the solution of many diseases, or preceded and, as it were, announced their favourable issue, or, on the other hand, their termination in death; these circumstances or states came to be spoken of as constituting what was called a *crisis*, (from *κρίσις*, judgment,) and the days on which they were most generally found to take place were termed *critical days*. This language still prevails, even among those who are less inclined than ourselves to credit the ordinary restriction of such occurrences to distinct periods.

Certain changes, often noticed as preceding death, more especially in chronic diseases,—hiccups for instance,—and which are therefore considered and called critical, do also, if any faith may be reposed in popular observation, sometimes recur, increase, or alternate with other critical changes, at periods answering to that when the first warning of that kind appeared. If physicians place no reliance on such testimony, we are inclined partly to attribute it to their being seldom long engaged in watching maladies at the bed-side, where the senses and thoughts naturally become concentrated on the events of the sick chamber alone. Our own observation in the course of country practice, and in cases where circumstances have occasioned our attendance to be close and protracted, has, we must candidly own, gone some way to corroborate the popular evidence on these points, which are certainly not of a nature to be made familiar to those whose chief knowledge of disease is acquired in formal consultations, or in daily visits to the wards of public institutions. No harm can arise, at all events, from directing the practitioner's attention to a subject which can only be investigated by a close attention to all the phenomena of ordinary sickness.

In the progress of a fever, the recovery or the fatal termination is doubtless often preceded by

some new action exemplified in the state of the bowels or of the skin. The sweating stage of an intermittent will occur to every reader as an example; but analogous phenomena often characterise those fevers which are denominated continued. Some are also distinguished by critical eruptions, of which the appearance relieves the febrile state. Certain conditions of the cutaneous or respiratory functions, productive of a peculiar odour of the breath or perspiration, are well known to practitioners as indicative of an aggravated malady.

Inflammatory disorders sometimes suddenly and happily terminate on the supervention of catharsis; whilst the common termination of inflammation in abscess is itself often spoken of as critical; so that to this day we hear of crude abscesses, of the digestion of the pus, and, among the older members of the profession, of the coction of the matter. Nervous affections, dependent probably in such cases on a plethoric state of portions of the nervous system, often for a time disappear immediately after an attack of epistaxis, or, in females, on the appearance of the catamenia after suppression. The accession and the departure of a paroxysm of hysteria or of asthma is sometimes marked by a copious flow of limpid urine; and a very free excretion of mucus from the bronchial membrane forms the common and true crisis of the asthmatic fit. Countless illustrations might be accumulated, but no one conversant with disease can have failed to remark them.

According to doctrines now very little regarded, these and numerous other phenomena acquired an additional importance from being considered indicative of the successful or unsuccessful results of a supposed struggle in the system for the expulsion of a morbid matter; a supposition which, in many cases, is so far from being in any degree unphilosophical, that it rests on facts too plain and of too frequent occurrence to admit of the least dispute. The terms crudity, digestion, and coction, have however been conveniently laid aside, as communicative of a sense which was not sufficiently exact.

The days on which the critical events are to be expected, have been variously named by different observers. This discrepancy, and, indeed, the chief difficulty in ascertaining, by actual observation at the bed-side, the truth or incorrectness of the ancient belief, arise from the same cause, namely, the uncertainty so often existing respecting the day on which any given disease actually commenced. In fevers, the first day is sometimes sufficiently marked, but not uncommonly it is impossible to determine when the general disorder was really advanced to the febrile condition. We should ourselves venture to direct the attention of those anxious to investigate this curious subject, to the third, fifth, seventh, eleventh, fourteenth, and twentieth days of our common fevers; and we think their attention will not go quite unrewarded.

The physician will, perhaps, find that in a considerable proportion of cases of continued fever, his services are first deemed necessary on the third day of fever, in consequence of symptoms indicative of a serious disorder then first becoming observable to the friends of the patient. Judicious

treatment will often assist in bringing about a favourable change on the fifth or seventh; or a decided improvement will occur between the eleventh and the fourteenth day: or be postponed until about the twentieth. Without affecting rigid exactness in respect to these days, or attaching extravagant importance to them, we have certainly thought ourselves justified in these conclusions respecting them, by observations made in circumstances not unfavourable to precise and undisturbed observation. The principle assumed is one which in numerous cases of disease is perfectly undeniable—that certain morbid processes are for the most part effected in definite periods of time.

It is not the object of the present work to collect the curiosities of medical literature; and we have therefore briefly dismissed this, among other subjects, on which it would be easy to prolong ingenious discussion. The practical application of the doctrine of a crisis is obvious. Its observation may conduce to exact prognosis; an art so difficult and deceptive, that all prudent physicians advise that the prognostic should be guarded with a care that may, in all cases, cause it “to quadrate with the event;” but at the same time an art in which the observant practitioner wonderfully excels those whose notice of the turns and changes of maladies is less diligent. Moreover, if a disease ordinarily terminates in some specific way, or in some specific crisis, the induction of that particular crisis becomes a wise indication for the guidance of the practitioner, although it will often be found that art cannot accomplish more than an ineffectual imitation of those critical evolutions which nature wants the power to perform.

Besides the property inherent in the body which may be assumed in many instances of periodicity to be the primary cause, there is an evident periodical influence exerted over many maladies by certain combinations of temperature, moisture, electricity, and other atmospherical properties, at different seasons of the year. There are individuals who in the spring of each year become maniacal; others in whom the heat of the summer seems to produce the same unhappy effect, and who are well in the winter. A tendency to vernal fever is very common in delicate women; and an aggravated dyspepsia, arising from gastric and intestinal irritation, is the frequent precursor, and apparently the exciting cause of many of the fevers of autumn, which are so commonly termed bilious; and with which some individuals are regularly attacked every year.

The influence of the heavenly bodies on the corporeal actions of the beings inhabiting this planet, the *lunar* and *sol-lunar* influences, once so reverently regarded, have been for some time past so often the subject of ridicule, as to make almost any allusion to them liable to the same reception. It would, however, be difficult to show, in the first place, any very good reason why animal bodies should be exempted from the operation of masses capable of acting on large portions, or on the whole of the globe on which they live; and abundant testimony, although not always, it must be confessed, very conclusive, might be collected in favour of views which have been too entirely discarded. That a lunatic should be under lunar influences, is an opinion now seldom

mentioned but to afford an opportunity for complacently contrasting the wisdom of the present time with the credulity of the past. Yet of those who have the charge of lunatics we have, we think, found the majority disposed to believe as their forefathers did. The determination of all questions of this kind requires such long and patient observation; there are so many collateral sources of deception, and the exceptions appear to be so frequent; that it is to be feared mankind will long continue to content themselves with unweighed assertions on the one hand, and indolent and contemptuous incredulity on the other.

**NOSOLOG.**—It was our intention to conclude this article with a view of the different *arrangements* of diseases which had been made by successive physicians since Aræteus first divided them into acute and chronic, unless, as is sometimes stated, Asclepiades is to be considered as having been the first deviser of nosology, many of his definitions being retained by Cælius Aurelianus. Galen, however, mentions Mnesitheus, who lived after Hippocrates, as having distinguished himself by the classification of maladies.

Conceding that the use of all nosological studies is really limited to the schools, and that to the practitioner they afford no immediate aid, it is yet not uninteresting to see the way in which some of the greatest men who have ever cultivated physic have attempted to reduce the innumerable diversities of disease into something like order. Not to dwell on their divisions into those of the solids and fluids; into internal and external; into idiopathic and sympathetic; into protopathic and deuteropathic; into hereditary, congenital, and acquired; into those of infancy, childhood, adult, and old age; into those attacking men and women; into the salutary, the benign, the malignant, and the pernicious: and without insisting vehemently on the importance of the divisions into curable, incurable, and fatal; or, with regard to the seasons, into the vernal, those of summer, the autumnal, and those of winter; or into the sporadic and popular; or into febrile and non-febrile; or sthenic, or asthenic; or general and local: and passing over many other refinements of a like kind, too often based on erroneous theories;—it would be most unjust to forget the eminent services of Sauvages, the first of the modern nosologists, (1731,) and the frequent references to whose writings in this work sufficiently show the estimation in which he is yet held. The celebrated Linnæus also, in 1763, endeavoured to arrange diseases with the same regularity with which he classed the objects of botany, but with less success. Among the classes of Sauvages were anhelations, weakness, pains, and discharges, all of which are usually but the *effects* of disease. In the arrangement of Linnæus, fevers and syphilis are placed together, on the ground that both are contagious.

In the more complete attempt of Dr. Cullen, praised, and justly praised, as an estimable work by his successor, Dr. Gregory, catarrh and dysentery are placed together, because both are profusiva, or discharges. Dr. Cullen's nosological arrangement was succeeded by that of M. Pinel, which became as general in the French schools as that of Cullen had been in England. The

arrangements of Sagar, Macbride, Bang, Daniel, J. P. Frank, Sprengel, Hufeland, and many others, in whatever estimation they were once held, or whatever merit they possess, are now seldom referred to except by the curious. Even Cullen's nosology is almost unknown in the schools of London; and Swediaur, who tried to improve it, is no better remembered. Among the nosologists who have pushed the science to extremes, Vitet is sometimes alluded to, as placing in his sixth class, or diseases of *evacuation*, and in its fourth order, *of organised bodies*, accouchement, avortement—making pregnancy a disease, “beginning in conception, and ending in delivery.”

The name of the celebrated John Brown demands, at least, a passing attention. Dividing all disorders into sthenic and asthenic, he established on that bold foundation a superstructure of physic so ingenious, that, great as its defects were, and great the practical errors into which they led, they long attracted the regards and admiration of many of the most famous schools of Europe.

With more attention to the natural phenomena of the human body, with more practical experience and wisdom, but at the same time with a freer indulgence of fancy, Darwin attempted a new arrangement of diseases in the *Zoonomia*; a work in which, amidst a great variety of matter of very various value, the student will find many practical observations indicative of the penetration and genius of its distinguished author.

Dr. Bartholomew Parr, the author of the London Medical Dictionary, a work of great merit, and full of practical information, attempted to improve the nosology of Cullen, but little was gained by the attempt. Inflammations constitute his second class, and in it we find phthisis. In the profluvia we meet with cholera and diabetes. In the suppressorii, or suppressed functions, we find constipation, and asthma, and jaundice, and thirst.

These obvious inconveniences of artificial classification, which so many able persons have been so little able to avoid, show in an unanswerable manner the inutility of such divisions. If we were disposed to ridicule the science of nosology altogether, we might dwell on the nosology of Dr. Parkinson, who divided all diseases into hyperbiosis and catobiosis, and hoped “to obliterate the term fever from nosological language;” or we might turn to the *chemical* nosology of M. Baumes, of Montpellier, who classified maladies as calorinised, oxygenised, hydrogenised, azotinised, and phosphorensed. But any further consideration of the subject would be of little use to readers of any class.

If any arrangement is likely to be useful in a practical point of view, it would seem to be either that of diseases according to the *parts*, or the *functions* which they respectively most affect. The former is the arrangement followed by the present professor of the practice of physic in the London University; and the latter was followed by the writer of this article in the same chair. By observing either of these methods, the student's practical knowledge seems most likely to become conveniently and usefully arranged, so as to be retained with the greatest certainty, and referred to with the greatest facility; the first

inquiry of a practitioner who is investigating the case of a patient, being concerning the part or function affected. Some affections, as fever, being of a general character, are conveniently placed in a distinct class. The specious exactness of an arrangement proposed by Dr. Young, the learned author of the Introduction to Medical Literature, never sufficed to bring into general notice a system which was seen, at the first glance, to be without any practical utility; and the same general objection may well excuse our dwelling upon or detailing any particular system in a work like the present. The functional arrangement adopted by Dr. Mason Good might deserve particular notice, on account of the reputation of its author, were it not that his incredible prodigality of barbarous medical terms has made his nosological arrangement, if not quite confused and unintelligible, at least such as to defy the efforts of the strongest and most retentive memory. Having ourselves attempted a plan much less ambitious, and, as we believe, much more useful, it affords us no small gratification to find that the principle of that which is followed by a teacher of so high and deserved a reputation as Dr. Elliotson, is as nearly as possible the same. The only object of any consequence which it was ever pretended that nosology could effect, is the accurate discrimination of diseases. This cannot be taught by short definitions, but by full, and careful, and collated descriptions: and in order that such descriptions may be readily made and remembered, we believe that arrangement of diseases to be the best which causes those which affect the same organ to be brought close together. Their resemblances may thus be best compared, and their differences best observed; of which the result will be, that facility and accuracy of diagnosis which so greatly contribute to distinguish one practitioner from another; and, indeed, without which, no man, be his learning or his science what they may, can ever practise physic with success or satisfaction.

J. CONOLLY.

[DISINFECTANT; from *dis* and *infect*. This term has been restricted by some writers (Dr. A. T. Thomson, *Elements of Materia Medica and Therapeutics*, 2d edit. Lond. 1835) to those agents that are capable of neutralizing morbid effluvia. It is so employed by the author of the article *DISINFECTION*, in this work. The writer has always used it, however, to include antiseptics. These will be considered here;—the reader being referred to the next article for information in regard to the others.

ANTISEPTICS, as the writer has defined them elsewhere (*General Therapeutics and Materia Medica*, ii. 373, Philad: 1843), are “Substances that are capable of removing any incipient or fully formed septic condition of the living body, or of any part of it.” If we grant, that such a septic tendency may exist in the organism, under particular circumstances, we can conceive that antiseptics may be needed in two contingencies: *first*, to obviate such tendency, and *secondly*, to correct the offensive character of any of the tissues or secretions that may have become putrid, and thus prevent them from re-acting on the system. Generally, the acceptation of antiseptics includes

nly agents that are employed when signs of putrescency have already manifested themselves, and when the object is both to destroy the offensive character of the tissues or secretions, and to arouse the vital energies, so as to enable the functions of nutrition to take fresh activity, and throw off the morbid and morbid degeneration. With this view, the different vegetable tonics, and especially cinchona, with the mineral acids, are commonly exhibited, in order to induce a new action in the function of innervation,—and, through the improved hæmatisis, to enrich the vital fluid, so that, when it reaches the capillaries,—under the amelioration occasioned by these combined changes,—the organs of nutrition may assume fresh activity; and if a portion of the organism has become dead, and consequently extraneous, a separation of the dead from the living portions may be more readily accomplished. In this way, probably, most internal antiseptics act; whilst, by passing into the mass of blood, and being exhaled through the different emunctories, they may, at the same time, correct any septic condition or tendency which the different tissues or fluids have acquired. The action of some antiseptics cannot, however, be explained in this manner. This can obviously only be the *modus operandi* of such as enter the blood-vessels,—wholly or in part. Charcoal probably exerts its efficacy altogether on the first passages, and, through them, on the rest of the economy. It is difficult to conceive, that it can act through the medium of the circulation; whilst the chlorinated preparations, creasote, &c., produce their effect in the compound mode above described. In like manner, when these and other agents are applied externally to gangrenous or gangrenoid parts, their operation is equally complex. They first of all disinfect, by acting chemically on the parts with which they come in contact, and, as a general rule, stimulate the vital energies of the tissues, until these assume a new action, and throw off the morbid condition and degeneration. With this view, antiseptics are employed in gangrene, sphacelus, foul ulcers, &c. Some of them would seem to act merely as disinfectants: such is probably the case with charcoal; it merely destroys the putrid emanations, and thus prevents them from acting injuriously on the system.

Of the special disinfectants of the living body, the most important are the following:

*Sulphate of Alumina.*—The power, possessed by the aluminous salts, of preserving animal matter has only been appreciated of late years, and chiefly through the labours of M. Gannal; (*History of Embalming* &c. translated by Dr. Harlan: Philad. 1840.) M. Gannal prefers the simple sulphate of alumina, made by the direct combination of alumina and sulphuric acid. It has been chiefly to prevent putrefaction in the dead body, that the salts of alumina have been employed. They have, however, at the writer's suggestion, been used in the Philadelphia Hospital as antiseptics and detergents to foul, indolent ulcers, and with decided benefit; (*New Remedies*, 4th edit. p. 56. Philad. 1843, and *Medical Examiner*: Philad. 1843.)

*Chlorine*, in vapour, has been inhaled in gan-

grene of the lungs, in which it has been found to correct the fetor of the breath and expectoration, and to be, therefore, calculated to obviate not only the local but the constitutional symptoms. (Stokes, *Dublin Hospital Reports*, vol. 5.)

The aqua chlorini has been given in various cases as an antiseptic—as in typhus, scarlatina maligna, cancrum oris, gangrene of the lungs, &c. It has also been used, properly diluted, as a wash to foul ulcers—as a gargle in putrid sore throat, &c.

*Chlorinated Lime* and *Chlorinated Soda* have been used in like cases.

The *Muriatic Acid* and *Empyreumatic Acetic* or *Pyroligneous Acid* have also been prescribed, both internally and externally, as antiseptics. The latter owes its main properties to the *creasote* which it contains. This last is rarely given internally: it is sometimes applied to foul, indolent ulcers, to prevent or correct the putrefaction of secreted matters, and to stimulate the parts to a better action. It is also used as a wash in gangrenous stomatitis; and as a collutory, when a fetid breath originates in the decomposition of matters in the mouth.

*Charcoal* is occasionally given internally, in septic conditions; but it is most frequently applied topically, as in dentifrices, and foul ulcers. All the different *tonics*, too, have been prescribed internally, as well as applied externally, in similar conditions. A poultice of powdered *cinchona* is a common application to foul ulcers, and to gangrenous parts; and a decoction of cinchona, with muriatic acid, is frequently used as a gargle in ulcerated sore throat.

ROBLEY DUNGLISON.]

**DISINFECTION.**—This word, being in some degree new to our language, is here used to express the operations by which we attempt to clear the air and other bodies from the contamination of certain minute particles, some perceivable by the sense of smell, others not to be thus recognised, but all producing deleterious effects on the human system. Of those perceptible to the sense of smell the chemical qualities are in general more or less known to us; of those too, which are not to be thus perceived, we possess some chemical knowledge; but of others we know nothing excepting their deleterious effects on the human system, and occasionally on that of inferior animals. (See **INFECTION**.)

However various the sources of contamination, the means which have been resorted to for their correction are reducible to three heads: first, diluting, with pure air, the atmosphere of the infected apartment or place; secondly, the admixture of certain gaseous matters with such an atmosphere, in order to decompose the infecting particles: or attempting to divest the atmosphere of them by substances which have an absorbing power; thirdly, clearing, by washing, cleansing, and exposure to the air and to disinfecting agents, the solid matters, such as bed and body clothes, the walls of apartments, &c., of the noxious matters with which they might infect the atmosphere by slowly giving them out to it.

1. Diluting with pure air (for the means of accomplishing which see **VENTILATION**) is the

measure which, in all cases admitting of correction, merits the most confidence, and without which all other means are nugatory. It is the sole proceeding resorted to in cases in which the atmosphere of any place is rendered deleterious to life by the admixture of considerable quantities of noxious gases, as of carbonic acid produced by vinous fermentation, the combustion of charcoal, or the decomposition of vegetable matters in a close place; or of carburetted hydrogen, which is occasionally so copiously evolved in coal-mines; or where the wholesomeness of the air is impaired simply by the destruction of its oxygen, as occurs in the acid fermentation; or where great numbers of persons are assembled in a place comparatively small.

2. The decomposition of the infecting particles has been accomplished from an early period. Large fires were formerly kindled in the streets of a town where pestilence was prevailing, with this view; but it seems more than questionable whether they can in such a situation produce any beneficial effect whatever, and by enlightened people they are now entirely abandoned. In a limited quantity of air, however, as in an apartment, or the hold of a vessel, they may be useful, not by acting chemically on miasmata, but as a ventilating process, by causing a current of air in such situations; the heated and consequently light air ascending through the chimney or any aperture which may exist, and being replaced by a portion of that from the exterior. The firing of gunpowder in the open air, which has been occasionally resorted to, seems destitute of any effect, for we cannot expect any beneficial chemical action from the azote, carbonic acid, sulphate and sulphuret of potash, which are its products; neither can there be hoped from it any movement of the atmosphere sufficiently general to be of service; but in a limited space, by expanding the air, it may certainly cause it to be replaced by a portion of the cooler and more condensed external air. Fumigations with certain aromatic substances, as camphor, benzoin, &c., have enjoyed a degree of reputation probably unmerited, and founded solely on their property of disguising unpleasant odours; but they are now superseded by measures deemed more scientific, which we shall proceed to consider.

**Quick-lime.**—This substance, besides its well-known property of absorbing carbonic acid, which is copiously evolved from putrefying masses, appears, too, to absorb other gases which are the result of putrefaction; at least it has the quality of correcting offensive odours. From its power in this way, and probably from a supposition that it decomposes or absorbs miasmata, it is usual to pour it into privies or drains which emit offensive odours; and when pestilential diseases are prevailing to an extent to cause great mortality, it is customary to throw a thick bed of this substance over the corpses in the grave or trench in which they may be deposited. It is applied, too, in the form of whitewash to the walls of apartments, in which persons ill of febrile disorders have lain, as a security against any contagious matter which may have adhered to them.

**Charcoal.**—This substance, as is well known to chemists, possesses the property of absorbing

gases, and might, on this account, be advantageously employed to rid a limited portion of air of hydrogen or other offensive matters with which it is impregnated. It has not, however, been employed in this way; but the utility of charcoal filters in divesting water of any gases, the products of animal or vegetable decomposition, with which it is contaminated, has long been recognised.

**Acids.**—These have long been supposed to have the power of decomposing contagious matter, or in some mode depriving it of its virulence. The well-known *thieves' vinegar* owed its popularity to this supposed property; and it is still the custom to dip into vinegar letters and papers which arrive from places where pestilence is prevailing. Clothes and goods of all kinds, coming from lazarettos, are exposed to the vapours produced by the slow combustion of sulphur (sulphurous acid). But the former being thought too feeble, and the latter having been found exceedingly irritating to the lungs, they are rarely employed for general disinfecting purposes; and when acids are used, either the muriatic, the oxy-muriatic (chlorine), or the nitrous is resorted to, though the employment of any of them in an inhabited apartment is not unattended with serious inconvenience to patients and attendants.

Muriatic acid was first employed by Guyton Morveau, in 1773, to disinfect the principal church of Dijon, the air of which had become so contaminated by the emanations from the vaults below, from which, on account of their too crowded state, the bodies had been removed, that it was utterly unfit for divine worship. Vinegar, aromatics, and the deflagration of nitre had been tried without effect; but the vapour arising from the decomposition of six pounds of common salt by two of concentrated sulphuric acid deprived the air in one day of all unpleasant odour, and in four days afterwards worship was performed. This distinguished philosopher, towards the close of the same year, used fumigations of muriatic acid with complete success for disinfecting the prison of Dijon, whither fever had been imported from other gaols, of so malignant a nature that thirty-one prisoners had perished from it in a very short space of time.

The proportions recommended are twelve parts of sulphuric acid of the specific gravity 17 to fifteen parts of muriate of soda, which should be slightly moistened before the acid is poured upon it. If employed for disinfecting an uninhabited place, flat earthen dishes, containing the mixture, may be placed on a sand-bath, and the whole of the acid may be added at once. If in one occupied by patients or others, all heat should be dispensed with, and the acid should be added gradually. The latter rules should be considered imperative in all cases where acids are employed to disinfect inhabited places.

Nitrous acid fumigations were first employed in this country; and a liberal parliamentary grant was bestowed on Dr. Carmichael Smyth for their application to disinfecting purposes, which was regarded as a discovery. A prior claim was subsequently set up for Dr. Johnstone, of Worcester. The fumigations were successfully employed by Dr. Smyth in 1780, for checking the progress of a fever which prevailed among the Spanish pri-

soners at Winchester, of whom it had destroyed a seventh part in three months. Several other examples of their utility in disinfecting ships and hospitals might readily be quoted. Nitre and sulphuric acid are the substances employed in this mode of fumigation, and equal parts of both ingredients are found to be the best proportions. The combination of the salts producing a considerable evolution of heat, none should be employed to aid the decomposition. It is calculated that half an ounce of each ingredient will suffice to disinfect an apartment of ten feet in each dimension, comprising of course a thousand cubic feet; and it is advised, in case of our having to apply the method to larger apartments, that we should multiply the cups or saucers which contain the ingredients, rather than introduce a larger quantity than that mentioned into one vessel, as the red fumes disengaged might seriously incommode the operator.

Oxygenated muriatic acid (chlorine) was first proposed as a disinfecting agent by Fourcroy, in 1791. It was soon after employed by Cruickshank, of Woolwich, and by Guyton Morveau, who thought it preferable to all other acids; and it has since united most suffrages in its favour. There is an excellent and concise account, in the eighteenth volume of the *Journal of Science and the Arts*, of the disinfection of the *Milbank Penitentiary* by Mr. Faraday. To this the reader is referred, as it comprises all that is necessary to be known of the mode of applying fumigations of chlorine to uninhabited places. The following are the material points of the process adopted by Mr. Faraday. He found that one part by weight of common salt, and one part of oxyde of manganese, when acted upon by two parts of oil of vitriol, previously mixed with one part by weight of water, produced the best results. The salt was bruised down with a mallet previously to being mixed with the manganese; and the acid and water were mixed in a wooden tub, and allowed to stand for some hours, that the heat produced by their combination might be dissipated before they were poured on the other ingredients. Common red pans, of a flat form, were used for the fumigation. The evolution of chlorine commenced a few minutes after the ingredients were mixed in the pan, and continued for four days, no extraneous heat being employed in the operation. The quantity of material used was 700lb. of salt, 700lb. of oxyde of manganese, and 1400lb. of sulphuric acid; whilst the space requiring fumigation amounted to nearly 2,000,000 cubic feet, and the surface of the walls, floors, and ceilings was about 1,200,000 square feet. The able arranger of the process is of opinion that from one-half to one-fourth of the chlorine, and consequently of the ingredients employed for its production, would be quite sufficient in a building of the same extent, for any of the usual cases where fumigation is required. The proportions recommended by Guyton Morveau differ from those employed by Mr. Faraday. The former philosopher advised that two parts of powdered oxyde of manganese should be mixed with ten parts of muriate of soda, and that the mixture should be acted upon by six parts of sulphuric acid previously diluted with four of water; and in an uninhabited room, forty feet by twenty, he

thought two ounces of oxyde of manganese, ten ounces of muriate of soda, six ounces of sulphuric acid, and four ounces of water, sufficient for perfect disinfection; the doors and windows being closed for ten or twelve hours.

Chlorine is so powerful an irritant to the bronchial lining, that its rapid evolution in the processes described above is quite inapplicable to inhabited apartments or wards, unless the quantities of the ingredients employed are so small in proportion to the space to be disinfected that we cannot expect any beneficial result from them. Guyton Morveau endeavoured to surmount this difficulty by means of his permanent apparatus of disinfection, which consisted of a glass vessel encased in wood, having its mouth very accurately closed by means of a ground glass stopper, acted on by a vice. A slight turn of the vice allowed the vapours, by their expansive force, to raise the stopper and mingle with the atmosphere. One-third of the apparatus was occupied by four parts of oxyde of manganese, finely powdered and sifted, ten parts of nitric acid of sp. gr. 1.40, and ten of muriatic acid of sp. gr. 1.134. From this combination the chlorine is disengaged much more slowly than by the action of sulphuric acid on a mixture of muriate of soda and manganese; and by means of the vice the issues of gas are regulated at pleasure, whilst the lightness and closeness of the apparatus enable us to remove it readily from one place to another. The disinfecting bottle, arranged in the manner described, may be opened twice a day, and still retain its disinfecting power for three or four months. However ingenious the plan of M. Guyton Morveau, this, and perhaps all disinfecting processes—certainly all for occupied wards or apartments—are superseded by the agents more recently introduced by M. Labarraque. This gentleman, an apothecary in Paris, was the first to suggest the employment of chlorine in a liquid form for disinfecting purposes. He recommends two solutions. One, the chloride of lime (a solution of bleaching powder,) is prepared by passing chlorine gas over hydrate of lime: this, when dissolved in water, forms Labarraque's liquid; or the liquid may be formed directly by passing the gas into water which holds lime in suspension. Two methods are recommended for forming chloride of soda, one by M. Labarraque, and the other by M. Payen. The former passes chlorine gas into a solution of carbonate of soda; the latter decomposes chloride of lime by the carbonate. Both processes are easy, the latter the most so; and it has been so arranged by M. Payen as to make the resulting compound identical with that prepared by the former method. No carbonic acid is expelled on passing the chlorine into the solution of carbonate of soda; the solution has a faint smell of chlorine; when heated, scarcely any chlorine is evolved; it first acts as an alkali on turmeric paper, and then bleaches it; on the addition of acid, chlorine and carbonic acid are expelled.

Chemists do not seem fully agreed as to the precise nature of these compounds, but in a practical work we do not feel called upon to enter into controversies on this point. (See *Granville in Journal of Science*, &c. vol. xxiii. and *R. Phillips in Philosophical Magazine*, vol. i. of New Series.)

It is material to know that they are most powerful disinfecting agents, and that since their introduction by Labarraque they have been applied to every kind of case in which the operation of such agents is requisite, by innumerable scientific persons of various nations, whose testimony is loud in their favour. They appear to act, as the experiments of Gaultier de Claubry tend to prove, by the evolution of chlorine, from the action of the carbonic acid contained in the atmosphere on the compounds, so that a gradual fumigation by chlorine takes place; and where atmospheric impurities abound, the proportion of carbonic acid being generally greater, the fumigation will be more rapid. The following is an abstract of these experiments:

Well saturated chloride of lime being dissolved in water was submitted to the action of carbonic acid gas; chlorine was quickly disengaged, and by continuing the operation a sufficient length of time, the whole was expelled, the liquor no longer possessing bleaching powers, and carbonate of lime having been precipitated.

Air, passed slowly through a saturated solution of caustic potash, to deprive it of carbonic acid, was then made to traverse a solution of the chloride of lime; no chlorine was liberated, no effect of any kind produced.

The chloride of soda is equally decomposed by carbonic acid, only more slowly, in consequence of the solidity of the salt produced.

A filtered solution of the chloride of lime was exposed to the air on the 13th of August; on the 10th of October it no longer contained chlorine; did not affect litmus; and the precipitate from it proved to be carbonate of lime. A stronger solution of the same chloride, exposed to the air on the 16th of August, was found in the same state as the last on the 10th of October.

Air was passed through blood, which had been left to putrefy for eight days; being then passed through a solution of the chloride of lime, carbonate of lime was deposited, and the air was rendered inodorous and completely purified. In a second similar experiment the fetid air was passed through a saturated solution of caustic potash before it arrived at the solution of the chloride; the latter then had no effect upon it, and the air retained its insupportable odour. Another experiment was made with air left twenty-four hours over putrescent blood; the portion of it which was passed directly through the chloride was perfectly purified, but when previously freed from carbonic acid, the chloride had no effect upon it. (*Annales de Chimie*, xxxiii. 171, and *Journal of Science*, vol. xxiii.)

These experiments of Gaultier de Claubry seem very conclusive, yet a fact is mentioned by Labarraque and Parton, in their report to the Council of Health of Paris, on the removal, from the church of St. Eustache, of the bodies which were deposited there during "the three days" of July, 1830, which tends to show that carbonic acid is not uniformly the agent which decomposes the chlorides and calls into action the disinfecting power of the chlorine. These individuals found this process go on very rapidly indeed, though a bed of lime thickly spread over the floor must necessarily have absorbed the carbonic acid; and

hence were led to conclude that an exact theory of the phenomenon still remains to be discovered. (See Report, &c. or abstracts of it in the *Medical Gazette* for January 1, 1831, which also merits perusal as showing the mode of applying the disinfecting liquid on a large scale.)

The chloride of lime is the preparation which M. Labarraque recommends for disinfecting apartments, while that of soda is especially employed, in topical and external applications, to foul wounds and ulcers, &c. It were needless to enlarge on what is so familiarly known, their power of delaying the occurrence of putrefaction, of arresting it when it has already commenced, and of purifying the tainted air of hospitals, prisons, lazarettos, ships, sick-chambers, sewers, drains, and manufactories in which animal substances in a state of putrefaction are used, and their consequent utility to the anatomist, physician, and, we may say too, police-officers and magistrates.

If an uninhabited place is to be disinfected, troughs or pans, which expose a considerable surface to the air, and containing the chloride of lime, are placed in various parts of the building; the same liquid is poured over the floor, and sheets wet with it are suspended in various situations. If an inhabited ward or apartment is to be kept clear of impurity, the floor must be frequently and freely sprinkled with it, and portions of linen moistened with it should be attached to the bed-curtains, window-hangings, &c. If a putrefying body is to be preserved, it should be kept wrapped in a cloth steeped in it; or, if one is to be exhumed, the same plan should be adopted, with a copious affusion of the liquid into the vault the moment it is opened. It may be poured freely into drains, privies, or night-chairs which emit an offensive odour; and foul sores may be frequently washed with the liquid chloride of soda, diluted, if necessary, with rose-water. The only inconvenience connected with their use is the unpleasantness of the smell of chlorine, which some patients declare to be worse than that which it is employed to correct; but they should be reminded that there is nothing pernicious to life in the smell of the disinfecting liquid, whilst the bad smell of the apartment betokens unwholesomeness.

The subject would be left imperfect did we not inquire into the extent of the power and the mode of action of acid fumigations, in which class we include chlorine, either directly applied or furnished by the chlorides, though not ignorant that the title of chlorine to be considered an acid is disputed by chemists, and though there may be still some doubt as to the mode in which the chlorides affect atmospheric impurities.

It will be at once understood that these agents can produce a beneficial effect only on a limited quantity of air, and that no epidemic constitution existing in the atmosphere of a district or country can be corrected by them. If they are to have any beneficial effect in checking the propagation of febrile diseases, the miasmata which engender such diseases must be existing in a limited space; for if the air which will necessarily replace that which has been disinfected partake of a general contamination, it is manifest that their employment can be attended with no good effect but that of correcting obvious nuisances, such as bau

smells. Hence, when these vapours have been employed to prevent the diffusion of a widely-spreading epidemic malady, they have uniformly proved inefficacious, as was shown by M. Nyssen and Professor Arejula regarding yellow fever, when it was prevailing in the south of Spain during the years 1800, 1801, 1803, and 1804. Cabanellas, it is true, who was sent by the Spanish government into Andalusia to employ them, thought favourably of their merits, but the weight of testimony is against him; and, besides, he did not employ them till the month of November, when the heat having abated, the intensity of the epidemic must, according to its known laws, have been diminishing. That, employed in a limited atmosphere, they have some effect in checking the spread of typhus, appears to rest on competent authority. Ignorant as we are of the nature of contagion, we are of course ignorant of any specific chemical power they possess of acting upon or decomposing it. All the stronger acids, as we know, possess the property of corroding the animal texture; and their power of acting on contagious matter which is of animal origin, may depend on this property, or on their quality of absorbing or decomposing the noxious gases, which are probably powerful vehicles of contagion, as it is ever found to be least active in the purest atmosphere. That in some way they act on the contagion of typhus rests on the testimony of Guyton Morveau, Carmichael Smyth, and a host of persons of note and character; but the feeling of the profession at large, and we believe that feeling to be a correct one, is that their power over it is limited, and does not supersede the necessity of avoiding needless approximation to the sick, and of adopting every measure of ventilation and cleanliness which art can supply.

That, in a limited atmosphere, they promptly destroy bad odours, is well ascertained, and of all modes of fumigation that with chlorine is the most efficacious in this way: but on what this property depends does not seem very well understood in the case of all of them. Chlorine combines readily with hydrogen, and combines with or decomposes its compound gases; it decomposes, too, ammoniacal gas, and hence there is not much difficulty in understanding how an agent which acts promptly on those gases, the result of putrefaction, and affecting strongly the sense of smell, should be powerful in correcting the more obvious nuisances of infected apartments. But it is not so clear how certain of the other disinfected agents, muriatic acid for instance, the affinity of which for septic gases is less general than that of chlorine, remedy such nuisances, though the experience of Guyton and many others places the fact that they do so beyond all question.

3. It is obvious that the solid matters which are in the infected apartment will receive the beneficial influence of the fumigations employed to purify the air. In addition to this, they should be washed with soap and water, or an alkaline ley; the walls should be white-washed, and air be freely admitted for some time previously to the room's being again inhabited. All body and bed-clothes withdrawn from patients labouring under fever should be thrown at once into hot water, and either remaining there for some time, should be

thoroughly washed with soap or an alkaline ley. They should then be hung up in the air for a considerable length of time, and they may be occasionally sprinkled with the chloride of lime.

The ordinary mode of preparing the liquid chloride of lime is as follows:—Introduce into a common retort fourteen parts of black oxyde of manganese, six parts of muriate of soda, the same proportion of sulphuric acid, and twelve parts of water. The chlorine gas will rise without the application of heat, (though, if it is thought desirable to accelerate the operation, heat may be employed,) and should be transmitted through a tube attached to the neck of the retort to the bottom of a vessel filled with a saturated solution of lime. When this is saturated with chlorine, the test of which is the cessation of the evolution of gas from the materials in the retort, it contains about twenty per one hundred of this principle, and may be diluted with forty parts of water for ordinary disinfecting purposes. It is desirable to add the water shortly before employing it, as an extrication of gas commences rather rapidly immediately on the water being added.

The liquid chloride of soda is prepared in the same manner, a solution of one part of subcarbonate of soda in twenty parts water being substituted for the saturated lime-water. The absorbing power of this solution over the chlorine is less than that of the lime-water: hence, when used for disinfecting purposes, the liquid chloride of soda should be diluted with only thirty parts of water.

The materials employed for impregnating one or the other of these liquids with chlorine, may be frequently made to evolve more of this principle by the addition of more sulphuric acid, and thus successive quantities of the chlorides may be formed from the same ingredients.

Dr. Henry, of Manchester, has recently performed a series of experiments, which seem to prove that the fomites, or materials impregnated with the infectious principles of various contagious diseases, may be rendered totally inert by exposure to elevated temperatures. Dr. Henry first ascertained that raw cotton, and various kinds of piece-goods manufactured from that or other materials for clothing, are injured neither in texture nor colour by exposure for several hours to a dry temperature of nearly 212°, or even 250°, Fahrenheit. He next ascertained experimentally, that vaccine matter, though capable of communicating the disease after exposure to 120° Fahrenheit, is rendered inert by a temperature of 140°. In the third place, he found that a flannel shirt, which had been worn by a patient in well-marked typhus between the tenth and eleventh days of the disease, was, after exposure for an hour and three quarters to a temperature of 204° Fahrenheit, incapable of communicating the disease to a person, below whose nostrils it was placed for two hours; that a second flannel waistcoat worn on the night between the eleventh and twelfth days, and heated in the same manner, and worn for two hours by the same individual, did not communicate the disease; and that a third worn by the patient on the night between the twelfth and thirteenth days, after exposure to heat and seclusion in an air-tight canister for twenty-six days, was equally incapable of communicating

fever. In the fourth place, he found that a series of eight flannel waistcoats worn for several hours by patients in distinctly marked scarlet fever, afterwards exposed to heat varying from 200° to 204°, and eventually worn for several hours by children not having had scarlet fever, did not communicate the disease to these children.

Dr. Henry expresses himself with a degree of caution respecting a positive conclusion being deduced from his experiments on the contagious principle of typhus; but thinks his experiments sufficiently numerous to prove, that by exposure to a temperature not below 200°, during at least one hour, the contagious matter of scarlatina is either dissipated or destroyed. He is more inclined, however, to the latter than the former supposition, because cow-pock matter, though completely deprived of its volatile portion at 120°, is not rendered inert by temperatures much below 140°.

As a disinfectant of articles which are capable of imbibing and retaining contagion, heat, the author suggests, is greatly superior to the vapours or gases used for the same purpose; inasmuch as the transmission of the latter may be stopped by a few folds of compressed materials; while heat, if time enough be allowed, finds its way in spite of all obstacles. He limits the application of the method to the destruction of contagion existing in substances technically called "susceptible;" for instance, to infected clothing of every description; to infected bedding and bed-furniture of every kind that would be spoiled in washing; to trunks and other packages brought by travellers from infected places, and to merchandise whenever it can be shown or rendered highly probable that such merchandise has been in the way of imbibing contagious matter. The apparatus recommended by Dr. Henry is simple, and seems well calculated for the object he has in view. It consists principally of two vessels of copper, or tinned iron, between which steam, the agent employed for transmitting heat to the infected materials, is introduced: but for a full description of the apparatus, and for the plate in which it is represented, we must refer to the *Philosophical Magazine and Annals of Philosophy* for January, 1832.

In a matter of so much importance, and, we would add too, of such extreme difficulty, it appears desirable that a more ample series of experiments should be performed on the contagious principles of typhus and scarlatina; and that we ought not to rely on mere analogy as a reason for extending to other contagions the procedure recommended, but that these ought likewise to be made the objects of experiment.

JOSEPH BROWN.

**DIURETICS**, (*Diuretica*, Φάρμακα διουρητικά, from διὰ and οὐρέω, μέιο: *Th. οὐρον*, *urina*.) medicines which augment the urinary discharge. This definition might be considered defective, as being too general, but it is the only one that can be admitted; for the excretion of urine, under the influence of diuretics, does not always arise from a direct application of the diuretic substances to the kidneys; but, frequently, from circumstances connected with the state of the stomach, and other

organs, under which the kidneys act only a secondary part.

Diuretics are supposed to operate in four distinct ways: 1, by passing into the circulation, and, being conveyed to the kidneys without undergoing any decomposition *in transitu*, acting directly as stimulants on the urinary organs; 2, by suffering decomposition *in transitu*, and acting on the kidneys by one or more of their constituents; 3, by acting primarily on the stomach and *primæ viæ*, communicating their action to the kidneys by sympathy; and, 4, by stimulating the disordered capillary system to more healthy action,—thereby preventing the undue effusion of fluids into the serous cavities, and permitting the absorbents to convey those already effused into the circulation, to be discharged by their natural excretories the kidneys.\*

1. In the healthy and ordinary condition of the body, the blood which is sent to the kidneys is divided into innumerable streams, each of which, entering the glandular glomerules of which these organs are principally composed, supplies the pabulum from which the urine is secreted; whatever, therefore, is conveyed to the kidneys through the medium of the blood must, more or less, affect the natural function of these organs. Thence the inquiry, in what manner is this effected?

If we analyse the urine, we find that it consists of water; urea, a peculiar compound of nitrogen, oxygen, carbon, and hydrogen; small proportions of sulphates of soda and potassa; phosphates of lime, soda, and ammonia; muriates of soda and ammonia; lactate of ammonia and fluato of lime. Knowing that these are the components of urine, it is not difficult to ascertain what substances have passed through the kidneys, and whether these have undergone decomposition. Thus, if free potassa or nitrate of potassa be taken into the stomach in moderate doses, and be afterwards detected in the urine, we may conclude that they have been conveyed to the kidneys through the blood, as they could not otherwise be found in the excretion of these organs. The excretion, however, of these salts does not take place without the kidneys experiencing the influence of their stimulating qualities, and consequently having their natural action so much augmented that a larger than usual supply of urine is the result. On the knowledge of this truth, the first division of the preceding arrangement may be said to be constituted. It is nevertheless a curious fact that, although these substances can be readily detected in the urine, yet they cannot be discovered in the blood; neither can colouring matters, which are easily displayed in the urine, be rendered evident, either in the blood or in the chyle. A doubt was suggested as to the medium through which such matters are conveyed to the kidneys by Sir Everard Home, who imagined that they found their way through the spleen; but he afterwards properly abandoned this opinion, on finding that, after removing the spleen, and tying the thoracic duct, the colouring matter of rhubarb in

\* This plan of the mode in which diuretics operate is a modification of that of Dr. Paris, (*Pharmacologia*, vol. i. p. 167,) which in its turn is a modification of that suggested by Dr. John Murray, (*Materia Medica*, vol. i. p. 366-8.)

jected into the stomach of a dog could be detected in the urine. It is sufficient, however, for our purpose, to know that substances taken into the stomach are conveyed to the kidneys;\* and that, if they are of a nature to stimulate these organs, provided the stimulus be short of that necessary for exciting inflammation, an increased secretion of urine must follow. It is indeed perfectly obvious that the stimulant influence of diuretics must be within a certain limit; for were the excitement of the kidney sufficient to induce inflammatory action, the urine, instead of being augmented in quantity, would be scanty, high-coloured, and acrid; a fact of great practical importance.

It may not be improper to remark, in this place, that the chief intention of the renal secretion is, probably, the excretion of urica. When both kidneys are taken away from a dog, the animal dies before the ninth day; but, previous to death, the serosity of the other secreting organs affords traces of the presence of urine in it. In reply to this mode of reasoning, it is stated that, in a healthy condition of the body with the kidneys entire, urica has been detected in the perspiration; and that there are instances of persons having passed no urine for many years together, and who yet have suffered no inconvenience;† but these are exceptions to a general rule.

Much of the fluid ingesta passes off by the kidneys, and the quantity of urine excreted is generally proportionate to the quantity of fluid taken into the stomach; thence the necessity of dilution to promote the operation of diuretics. None of the substances possessing diuretic properties require the aid of dilution so much as those in the first division of our arrangement. Without this they would scarcely be conveyed to the kidney, and, if they were, the over-excitement which would be induced would check rather than promote the increase of the urinary secretion.

The action of diuretics is, also, much modified by the function of the skin. When a diuretic is administered, the surface should be kept cool; for if the cutaneous exhalents be stimulated by heat, the medicine determines to the surface, by that law of the system which regulates the balance between the skin and the kidneys as excretories, and sweating supervenes with a diminished discharge of urine; just as in the healthy state, in cold weather, when the surface is chilled, the urine is abundant and pale, whilst in warm weather, when perspiration flows freely, it is scanty and high-coloured. On this account the season of the year, and all circumstances influencing the function of the skin, modify the operation of direct diuretics.

2. Many vegetable bodies and some salts which operate as direct diuretics, undergo digestion, to a certain extent, and only one or more of their constituents reach the kidneys. It is a curious fact,

however, that the saline bodies which undergo decomposition in transitu are those into which the vegetable acids enter as components. The acid, which is separated, is decomposed and resolved into its primary elements as if it had been swallowed in its free state; and the alkali being taken into the circulation, is conveyed undecomposed to the kidney, and excites that action in it which promotes the secretion and excretion of the urine. This remark, however, as we shall afterwards prove, is not generally correct; for some salts, compounds of vegetable acids with alkalies, bitartrate of potassa, for instance, operate in a manner which cannot be explained upon the supposition that its alkali only is conveyed to the kidneys. The neutral salts containing the mineral acids are not decomposed, but operate as direct diuretics, as has been already described. Dr. Paris seems inclined to believe that the *bitter principle* is the active ingredient of the vegetable diuretics, which are decomposed by the digestive organs: we are not prepared to deny the accuracy of this opinion; but, if we may reason from analogy, we should be disposed to ascribe the effect to some alkaline principle, which it is probable all of them contain. That other principles of vegetable bodies are separated during digestion, and carried to the kidneys, is evident from the odour which garlic, turpentine, asparagus, and some other vegetable matters impart to the urine; and as these are diuretics, it is not improbable that they possess this quality from the principle, whatever it is, which is combined with or constitutes the odorous matter.

Salts containing vegetable matter in excess, are more diuretic than those which contain the same acids in proportions only to neutralize the alkaline bases with which they are united, in proportion as they are more susceptible of decomposition. Thus, whilst bitartrate of potassa is diuretic, the neutral tartrate is purgative, and exerts no action on the kidney. Something, however, is due to the extent of the dose in which the salt is administered; many substances in small and moderate doses operating as diuretics, which, in large doses, operate as cathartics. This is the case with bitartrate of potassa. Oil of turpentine in doses of ten or fifteen minims up to a fluidrachm, stimulates the kidneys so powerfully as to cause bloody urine, yet a fluidounce purges and produces no perceptible effect on the urinary organs; and in the same manner, when nitrate of potassa has been taken in large doses by mistake for sulphate of magnesia, the symptoms do not indicate any affection of the kidneys.

3. With regard to the third description of diuretics, those which augment the flow of urine, without acting directly on the kidneys, we find that they are substances which, augmenting the nervous energy, give an impulse to the general vigour of the habit, and produce tone. In a weakened state of body the fluids in the serous cavities and cellular texture accumulate; and when the cutaneous system shares in the general debility, anasarca also is the consequence. In such conditions of the body, by augmenting the general tone, the urinary organs also acquire additional vigour; and thence diuresis and the absorption of effused fluids follow the administration of vegetable bitters and other tonics.

\* Alkalies are detected in the urine by testing it with turmeric paper; nitre by dipping a piece of bibulous paper into it, then drying the paper, and applying it to the flame of a candle; if it deflagrate, nitre is present. The odour of asparagus, garlic, turpentine, cubebs, and many other substances, is detected in the urine an hour or two after these substances have been swallowed.

† Dr. Richardson, in a paper published in the Philosophical Transactions of 1713, mentions a lad of seventeen, who had never made any urine.

4. The fourth division of diuretics is one of great importance, and contains, besides mercury, many diuretics, the action of which has been erroneously supposed to depend on their influence on the absorbent system. We shall examine this subject in detail, when we have occasion to speak of the substances that are arranged under this division.

Diuretics, from the increased discharge of urine which they induce, operate as evacuates; but, at the same time, they also exert a stimulant influence. As evacuates, they remove the general plethoric state of the system, and diminish excitement without inducing much debility; for, as the abstraction of fluid from the circulating mass is slowly effected, the vessels contract and gradually accommodate themselves to the lessened quantity of their contents. As evacuates also, diuretics are supposed to carry off acrimonious matters contained in the blood; but the existence of such matters in the circulating mass is very doubtful. As stimulants, diuretics act both on the general and the capillary systems, even when they exert a direct influence on the kidneys. As far as their effects depend on their stimulant properties, they are contra-indicated in all inflammatory states of the kidneys; in which states, and where much irritability is present, the simple diluent diuretics are to be preferred. Water is the best of these; how far it acts a part in all diuretics is not accurately known, but it has undoubtedly an influence in modifying their effects. There is no doubt that copious draughts of water, or any mild aqueous fluids, if not determined to the skin by external warmth, pass freely off by the kidneys, and thus produce an increased discharge of urine.

Among the diuretics which act primarily on the kidneys, without undergoing decomposition in transitu, we find some volatile oils. The **oil of turpentine**, one of these, in whatever manner it may be taken into the habit, rapidly displays its presence in the urine by the odour of violets, which it communicates to that secretion. Its effects, however, as we have already stated, are greatly influenced by the extent of the dose. In some idiosyncrasies it causes a cutaneous eruption closely resembling eczema, in which case it ought not to be prescribed. During its employment neither wine nor spirits should be indulged in, and the ordinary quantity of food should be diminished. **Cajeput** oil, and that of **cubeb**s and of **juniper**, operate in every respect in the same manner. They are all employed to excite the action of the kidneys in hydropic diseases; but in effecting this, it is probable that they also influence, generally, the capillary system. The oil of turpentine is the most useful of the three; thence the reason why good English gin is a superior diuretic to Hollands, being rectified on oil of turpentine instead of juniper berries. These volatile oils may be combined with sugar as an oleo-saccharum, and given in any bland fluid, the best of which is the bitter almond emulsion.

Among the inorganic substances belonging to this section of the direct diuretics, **iodine** stands foremost. The alcoholic solution or tincture is the form of the medicine most commonly employed. When administered internally in doses of from ten to thirty minims of the tincture, in a

glass of water, twice or three times a day, iodine stimulates powerfully the whole of the glandular system, and, in a special manner, the kidneys. The diuretic effects of iodine, in combination with its general influence on the glandular system, renders it a most useful remedy in ascites connected with diseased states of the liver and the mesenteric glands. Like foxglove, it does not act beneficially when the abdomen is tense; but after tapping and reducing the excitement by a judicious employment of the lancet, it rapidly displays its influence on the kidneys. It seems to be the only decided agent which we possess for stimulating the absorbents, and this extends even to their influence over healthy glands: both the mammæ and the testicle free from disease have in several instances nearly disappeared during its administration. The writer of this article has had occasion to remark its powerful influence on the absorbents most satisfactorily demonstrated in a case of diseased ovary, which, after tapping, and a course of alteratives with tincture of iodine, carried to the extent of sixty minims for a dose three times a day, was completely cured. In this instance, it is probable that the great advantage arose from the rapidity with which the iodine was thrown into the habit after the tapping, and whilst the flaccid sac remained as a kind of extraneous body in the abdomen. It has never proved useful in similar cases when administered during the turgidity of the ovarian tumor, the growth of which seems to be little connected with the general system, and to depend solely on the local action of its own vessels; the state of tension, therefore, being its natural state, it may be regarded in this condition beyond the sphere of action of agents affecting the general system,—a circumstance, however, which is set aside as soon as the fluid is discharged, and thence it is brought within the sphere of the influence of the iodine.

Some inconveniences arise from the employment of iodine in irritable habits. It causes febrile excitement, which is often accompanied with nausea, vertigo, and headach, and, occasionally, with dysenteric symptoms, and, at other times, symptoms resembling those of paralysis agitans. It, also, in some instances excites perspirations and gripings. Under such circumstances the use of the medicine must be suspended.

A milder diuretic than either pure iodine or its tincture is the *hydriodate of potassa* [**iodide of potassium**.] Owing to its solubility, it is administered in a saturated solution, in doses of *mxx.* to *℥i.* It is incompatible with salts of copper, of lead, mercury, or silver.

The only oxide which has a direct diuretic influence is *potassa*. In the form of the liquor potassæ of the British pharmacopœia, it may be administered in very large doses in bland, demulcent fluids. Its primary influence is exerted on the stomach: if any acid be present, it is neutralized; but if the alkali predominate, or no acid be present, it first acts as a sedative, allaying the morbid irritability of the stomach, and then entering the circulation, is carried undecomposed to the kidney, upon which it acts, and can be readily detected in the urine.\* As a diuretic, potassa is

\* It is detected by testing the urine with infusion of rhubarb or turmeric.

not extensively prescribed, owing to an erroneous opinion that it is injurious in large doses. The writer of this article, by gradually increasing the dose, has given one hundred minims of the solution of the London College three times a day, for several successive weeks. In these large doses its power in curing the most obstinate cases of psoriasis is very striking, and although its beneficial effects are not evident until it displays its influence on the kidneys, yet it has on no occasion produced any injurious effects. It is not much to be depended on in dropsical affections.

Among the neutral salts operating as direct diuretics, **nitrate of potassa** has long held a place. It passes unchanged to the kidneys, stimulating them to increased action, and augmenting rapidly the quantity of the urinary discharge. It can be readily detected unchanged in the urine, on which account it ought not to be administered in inflammatory affections of the urinary organs; but none of the diuretics can be less depended upon in dropsical effusions; even after the phlogistic diathesis has been subdued. It operates in doses of from *gr. xv.* to *℥ss.*, and requires to be largely diluted. The **chlorate of potassa** operates nearly in the same manner as the nitrate, but it is seldom prescribed as a diuretic. There is some uncertainty with regard to the manner in which **borax** (*sodæ sub-boras*) operates as a diuretic; but, from the smallness of the dose (*gr. x.* to *℥ss.*) required to act on the kidneys, we are disposed to think that it passes entire to these organs. It is readily decomposed by all the mineral acids, common salt, muriate of baryta, and nitrate of silver, all of which, therefore, are to be regarded as incompatible with it in prescriptions.

Those diuretics which undergo decomposition in transitu, and operate directly on the kidneys by one or more of their constituents, comprehend substances from the three kingdoms of nature.

The only animal diuretic is **canthariden**,\* [or cantharidin,] as contained in the blistering beetle, *cantharis officinalis*, and the *milabris variabilis*, which has lately been introduced from China. The canthariden has not yet been employed in its separate state as a diuretic, but the influence of the blistering beetle on the urinary organs has been long known. Hippocrates employed it in dropsies, and a celebrated diuretic of Tulpus consisted of the tincture of Spanish flies, cardamoms, and sweet spirit of nitre. The internal use of cantharides, however, requires the utmost caution, and when thus employed, whether in the form of powder or of tincture, the freest use of diluents of a demulcent kind is absolutely necessary. In the form of powder, cantharides, in doses not exceeding two grains, stimulate the kidneys, and cause an increased flow of urine; and it is singular that neither heat in the region of the kidney nor strangury is experienced in this case. They have been found beneficial in ascites, in old worn-out constitutions. When accidentally over-dosed and

inflammation of the kidneys supervenes, with bloody urine, insupportable pains in the abdomen, strangury, vomitings, or convulsions, the lancet must be freely employed, with copious dilution, and an enema of warm water, containing from *mxx.* to *f℥i.* of tincture of opium. The employment of oil must be avoided.

The **balsam of copaiba**, **cubebs**, and the fruit of the **juniper**, owe their diuretic properties solely to the volatile oil which they contain, and which, separated from their other components during the process of digestion, is carried to the kidneys, and augments their natural function; it may be readily perceived by their odour in the urine. Copaiba in an over-dose causes inflammation of the kidneys; consequently, it ought to be carefully avoided when there is the least tendency to ulceration of these organs. It may be administered either in a fluid or a solid form. In the first it is given, combined with mucilage and any bland fluid, in doses of from twelve to thirty minims; or the volatile oil, separated from the resin by distillation, may be rubbed up with sugar, and administered in bland fluids, as an oleo-saccharum, in doses of from ten to twenty minims. The solidification of the copaiba is best effected by magnesia, in which state it may be formed into pills;† or, for the same purpose, it may be formed into a soap, as the union of the alkali does not, in any degree, diminish the efficacy of the balsam. In moderate doses, from *gr. x.* to *℥ss.* of the powder, cubebs are diuretic; in larger doses they are purgative. It is probable that some of the benefit derived from their employment in gonorrhœa may be ascribed to the diuretic influence of the volatile oil so much increasing the urinary discharge as to enable it to wash out the virulent matter in the urethra. We are not aware that they have been employed in dropsical effusions.

In the same manner as the digestive organs separate the volatile oil of cubebs and juniperberries, they separate veratria, the active principle of the **colchicum autumnale**, and scillitina, that of the **scilla maritima**, from the powder of the dried bulbs of these plants. Although colchicum, in full doses, acts powerfully on the excretory ducts of the liver and the pancreas in the duodenum, and brings down a large quantity of bile into the intestinal canal, yet in small doses the veratria is separated, taken into the circulation, and stimulates the kidney. As a diuretic, however, it is less powerful than the squill, a circumstance altogether depending on its disposition to run off by the bowels. For diuretic purposes the tincture is the best preparation of the colchicum, as the alcohol takes up the gallate of veratria, which is less liable to pass the pylorus undecomposed than the acetate, which is always formed when either vinegar or wine is employed as the vehicle for taking up the active principle of the plant, and which passing the pylorus, and bringing down a large quantity of bile from the liver, almost invariably purges. Both the petals and the seeds of the colchicum yield the same active

\* Canthariden, in its separate state, is a white substance, in minute micaceous scales, insoluble in water and cold alcohol, but soluble in boiling alcohol, ether, and oil. The knowledge of its solubility in oil is a fact of much practical importance in cases of poisoning by cantharides, in which the administration of oil, by dissolving the canthariden, tends to diffuse the acrid influence of the poison, and consequently ought never to be resorted to.

† This is effected by mixing the balsam with one-third of its weight of magnesia, spreading the mixture upon a plate, and exposing it to the action of the air for ten or twelve days. It then becomes plastic, and may be readily formed into pills. The activity of the copaiba is not diminished by its union with the magnesia.

principle to alcohol, wine, or vinegar, as the bulb. The dose of the dried bulb, in powder, is from five grains to twelve grains, that of the tincture or the wine from *mxx.* to *mlx.*, and that of the vinegar from *f.3ss.* to *f.3i.* Upon the whole, however, the preparations of colchicum are much less to be confided in, where morbid accumulations of fluid are required to be lessened, than those of the squill; and it only proves useful as a diuretic when it exerts little influence on the intestinal canal. It, nevertheless, cures dropsies by its stimulant influence on the capillary system, and by its evacuant properties, when given in larger doses than those mentioned as fitted to secure its diuretic influence. Squill is given in substance to secure its diuretic effect; but it is generally prescribed in combination with calomel or the blue pill, or bitartrate of potassa. As a full dose given at first is apt to induce vomiting, it is preferable to commence with doses of a grain of the powder, gradually increasing the quantity to six grains, repeated every fifth or sixth hour. Cullen recommends the bichloride (oxymuriate) of mercury instead of calomel, as an adjunct to squill; but every intention is sufficiently answered by the calomel, and it is much less likely to irritate the bowels. If the combination of squill and a mercurial act on the bowels, the latter must be discontinued, and the mercury introduced by the surface. In some habits, owing to idiosyncrasy, squill excites an eruption on the skin not unlike nettle-rash, accompanied with severe gripings, cold sweats, and occasionally convulsions; in which case the use of the remedy should be discontinued, and cordials with opium administered. Squill is most useful as a diuretic, in doses not exceeding eight grains of the dried bulb: it is incompatible with the alkaline carbonates, astringent vegetable infusions, and solutions of the sulphate of iron.

A decoction of the twigs of the common broom, *spartium scoparium*, has been employed as a diuretic from time immemorial: although nothing is known respecting its active principle, yet whatever it is, the decoction seldom fails to excite the action of the kidneys. As little is known respecting the active principle of *sarsaparilla*, but it certainly affects the kidneys; the alterative influence, however, of this root, can scarcely depend on its diuretic properties; and amidst so many better diuretics, it might be rejected from the list without any inconvenience being experienced by its removal.

Amongst the inorganic diuretics which undergo decomposition in transitu, are **salts of potassa** and **soda**, the alkalies of which only are transmitted to the kidneys. The carbonate and the bicarbonate of potassa, although the one contains double the quantity of carbonic acid of the other,\* both operate nearly in the same manner as diuretics; a circumstance owing to the reduction of the

latter to the state of the carbonate, during its decomposition in the stomach. The dose of the carbonate is from ten grains to  $\text{3ss}$ , but it may be augmented to three drachms; the bicarbonate may be given in double that quantity. The properties of either, as diuretics, are not lessened by administering them in the state of effervescence with lemon-juice or citric acid; this acid being separated during the digestive process in the same manner as the carbonic; and if any febrile heat be present, this is the best method of administering these carbonates. The same opinion may be given of the carbonate and bicarbonate of soda, which, owing to their taste being less disgusting than that of the carbonates of potassa, are more generally employed as diuretics.

The acetate of potassa has considerable claims to attention as a diuretic, if it be not over-dosed, for in doses exceeding  $\text{3i}$ . it operates as a purgative. In small doses it may be conjoined with infusion of gentian, or that of any light bitter: it operates with more certainty in small doses frequently repeated, than in full doses taken at long intervals. We have seen it ordered in conjunction with bitartrate of potassa; but in this combination the diuretic influence of both salts is destroyed, and a tartrate of potassa is formed by the decomposition of the acetate, and the abstraction of the superabundant tartaric acid from the bitartrate, which purges. The bitartrate in small doses, from gr. x. to  $\text{ʒi}$ , is a much more useful and certain diuretic than any of the other neutral salts in this division of this order of medicines. We are by no means satisfied that the influence of this salt depends on its alkali finding its way to the kidneys; for, when we reflect that  $\text{ʒi}$  of the bitartrate contains gr. v. only of potassa, and that twenty minims of the liquor potassæ contain gr. vii. of potassa, and that the diuretic effect of the  $\text{ʒi}$  of bitartrate is much greater than that of *mxx.* of the liquor potassæ, there appears undoubtedly some difficulty in assenting to the accuracy of the theory which has been stated. The influence of the bitartrate in ascites is well authenticated, and every day's experience confirms the confidence which has been placed in its diuretic powers. The emaciation which the bitartrate causes when taken as ordinary beverage, however, depends on its operation on the intestinal canal. Bitartrate of potassa is beneficially conjoined with squill or colchicum, or with bitter infusions; or, if the salt, when administered alone, have weakened the digestive organs, in combination with tartarized iron. In cases connected with glandular obstructions, we have given it at the same time that iodine was externally applied in the form of an ointment, and always with benefit: and here the dose of the bitartrate may be the same as if the iodine were not employed. The soluble salt, formed by the union of the sub-borate of soda with the bitartrate of potassa, operates, also, powerfully as a diuretic.

Some very active agents are found capable of producing a diuretic effect on the system by stimulating the capillaries to more healthy action, and thus enabling the absorbents to take up fluids already effused in the serous cavities and cellular membrane, and to throw them upon the kidneys, their natural excretories. Tobacco is one of these.

\* Carbonate of potassa.

Potassa, 1 propor. . . . . = 48 or 68·57

Carbonic acid, 1 propor. . . . . = 22 — 31·43

Equivalent. . . . . 70 100·00

Bicarbonate of potassa.

Potassa, 1 propor. . . . . = 48 or 47·53

Carbonic acid, 2 propor. . . . . = 44 — 43·56

Water, 1 propor. . . . . = 9 — 8·91

Equivalent. . . . . 101 100·00

it was introduced to the notice of the profession by Dr. Fowler, for this purpose; and when administered in small doses, either in the form of infusion or of wine, so as not to nauseate, it has been given successfully in dropsy. No diuretic, however, requires so much caution in its administration under the most favourable circumstances; and, therefore, it has been less employed than it deserves to be.

Much of the efficacy of **foxglove** depends on the period of the growth of the plant at which the leaves are collected, and the manner of drying and preserving them. In the months of July and August they are in the best state: they should be then gathered, and dried between colourless bibulous paper, in a warm room, and under a moderate pressure. This may appear to be an unnecessary degree of care and trouble, but for the preparation of a medicine of so much activity, and which is administered in grain doses, too much attention cannot be bestowed to preserve all its medicinal powers in the only way in which they can be obtained. When the dried pulverized leaves lose their green colour, some chemical change has taken place in them which deprives them of their native properties. In employing foxglove as a diuretic, it should be recollected that its influence on the capillaries is not obtained in states of the habit exceeding the limits of the healthy standard of tone. In states below that point, it stimulates the capillaries, and diminishes the force and frequency of the pulse, and operates as a diuretic; for in dropsical effusions, whether those of ascites or hydrothorax, no benefit can be expected from the employment of foxglove, as long as any tension of the vascular system exists. It is after tapping and a reduction of arterial action, that decisive advantages are obtained from prescribing foxglove in hydropic affections. It is on the same principle that it is most useful in lax, pale, leucoplegmatic habits; and, if the disease be anasarca, in those cases in which pitting is left on pressure of the affected parts: thence, when this state does not exist, the system must be lowered by blood-letting and purging, before any advantage can be expected from foxglove as a diuretic. It has been found useful to combine it with mercurials, especially the blue pill; and pushing this far enough to affect very slightly the salivary glands: but in cases of either anasarca or ascites, the best adjuncts are bitartrate of potassa, acetate of ammonia, or colchicum; and in constitutions broken down by protracted courses of mercury, the nitric acid.

When foxglove is administered in the form of powder, the dose may be gr. i. repeated for the first two days at intervals of eight hours; after which the intervals should be lengthened according to the effects produced. An infusion made by macerating one drachm of the dried leaves in f.℥viii. of boiling distilled water, and f.℥i. of cinnamon water, for four hours, speedily produces the diuretic effects of the plant, when given in doses of f.℥i. repeated at intervals of five hours. The dose of the tincture should not at first exceed ten minims; but it may be gradually increased until its diuretic influence be perceived. The symptoms of an overdose are nausea, vomiting, vertigo, pulsation in the temples, a sensation

of heat throughout the body, sweating, sometimes diarrhoea, and occasionally salivation. One remarkable symptom sometimes occurs, a suppression of urine. The best antidotes, under such circumstances, are, ammonia, brandy and water, opium, and the stimulus of a blister applied over the pubis. One circumstance is particularly necessary to be noticed in prescribing digitalis—its power of accumulating in the system, like mercury, and suddenly exerting its specific effects when not expected. No medicine, therefore, requires to be more closely watched, whether it be given in moderate doses, long-continued, with the view of obtaining diuresis; or administered in gradually augmented doses, to lull delirium and procure sleep in mania. Whenever nausea is felt, it must be noticed and suppressed; for vomiting arrests the diuretic influence of the remedy.

Little requires to be said of **lactucarium** as a diuretic. It has been found useful in hydrothorax, and some other cases of dropsical effusions, by the German physicians; but in this country its place is much better supplied by foxglove.

All bitter tonics possess, more or less, diuretic effects; but the **seneka** root is perhaps better adapted for this purpose than any other: its influence is particularly felt in those cases in which the serous accumulations are the effect of general debility; as for example, those cases of asthenic ascites which sometimes follow acute diseases. In such cases, also, much benefit is obtained from the **ferrum tartarizatum**, which, besides operating as a tonic, has a direct diuretic influence, and has been found peculiarly serviceable in cases of anasarca connected with affections of the heart; but in these cases its employment must be preceded by purgatives and mercurials. With respect to the employment of **mercurials**, much benefit is derived from their aid in promoting the operation of other diuretics. Thus the diuretic effects of squill are rendered more certain when combined with calomel; and those of digitalis when united with the blue pill. In both instances the stimulant influence of the mercurials on the capillary system aids that of the active principle of the other diuretics, and more benefit seems to result from such combinations than when either is administered alone.

From the view which we have given of the substances most commonly employed as diuretics, the practical employment of them as remedial agents may be very briefly stated. In febrile affections much must be done before prescribing diuretics; but in long-protracted fevers, whether intermittents or continued fevers, if œdematous swellings occur, their use is indicated and must not be delayed. If they be prescribed during continued fever, it should be recollected that one of the most distressing occurrences in that disease is retention of urine; and, therefore, in prescribing diuretics, it is highly requisite to examine daily the state of the bladder. Most fevers in their termination display critical changes either in the quality or the quantity of the urinary discharge: under such circumstances, it becomes a question—how far are diuretics likely to favour such a crisis? At the commencement of fevers the urine is generally pale; it becomes afterwards high-coloured; and at the termination of a paroxysm, if

the fever be intermittent or remittent, or, when it begins to decline, if it be of the continued type, a sediment either lateritious or of a pale pink colour is deposited, and has been regarded as critical. But this sediment is to be regarded rather as the result of a certain catenation of actions, than as the excretion of any thing injurious to the habit; and, were diuretics able to promote it, they would be of no avail. Upon the whole, therefore, even as simple evacuates, diuretics are of little value, either in idiopathic fevers, or in acute diseases in which fever is a symptom. They have been advantageously administered in many chronic affections, especially those accompanied with eruptions on the skin; but the chronic affections in which their influence is truly beneficial are *dropsies*. This class of diseases depend on such an atony of the capillary system, that instead of the capillaries carrying forward the fluids they contain, they pour them out into the serous cavities, and thence the balance between the exhalation and absorption which exists in health being broken, the effused matter is accumulated to a degree which overpowers the absorbents. Diuretics are prescribed to cure dropsies in nearly every form; and do so by stimulating the capillary system, so that no fresh effusion taking place, the absorbents are enabled to take up the already effused fluid, and to throw it upon the kidneys, its natural emunctory. When success attends the administration of diuretics in dropsy, one advantage resulting from their employment over drastic purgatives and some other remedies is, the little debility which they occasion. If diuretics, however, be given alone, they are uncertain in their effects, and seldom in that case deserve more than the title of palliatives; but, as adjuncts to other means, they aid materially the evacuation of the effused fluid, and have thus frequently effected the removal of general dropsy. Their success, however, is very precarious; and so many circumstances interfere with their operation, that it is difficult to form a prognosis of their expected effects. Sometimes they operate freely, increasing greatly the discharge of urine, and yet the dropsical swellings continue. In this case some organic mischief must be looked for; and unless this can be removed, no great advantage can be expected from the evacuation of the effused fluid.

The kinds of dropsies in which *direct* diuretics have proved most beneficial are anasarca and ascites; whilst those which operate by diminishing arterial action, and augmenting that of the capillaries, are the best adapted for hydrothorax. But even in any case the influence of diuretics hinges upon so many accidents, that all of them are precarious in their effects. In encysted dropsies they are utterly useless, unless preceded by reducing the sac to the state of an extraneous body.

Diuretics have been much prescribed in calculous diseases; and most of the substances called lithontriptics are diuretics. We have ample proofs that none of them act chemically in dissolving calculi; nor, indeed, can they be said to be capable of effecting any change on the kidneys sufficient to prevent the formation of calculous matter. It is probable that the benefit accruing from their employment is wholly due to their influence on

the digestive organs; and by their aiding in the formation of a better gastric juice, the digestive process being rendered more complete, all the secretions, and consequently all the excretions, must necessarily become more healthy, and cease to deposit the uric and other acids in the pelvis of the kidney.

In conclusion, we would say that the efficacy of this order of remedies depends more on the tact of the prescriber, and his intimate acquaintance with the changes, both structural and functional, which disease produces on the system, than any other. The operation of no other order of medicines is so much modified by circumstances; and no other medicines require so much attention as these for insuring their beneficial effects. The following rules ought always to be strictly observed during the administration of diuretics.

1. The surface of the body must be kept cool.
2. The use of diluents is essential, and ought always to be urged, more especially when the saline diuretics are employed.
3. The patient should, if possible, be out of bed during their operation.
4. The diuretic should be administered in the day-time.
5. After the accumulated fluid has been removed from the serous cavities, and the use of the diuretics suspended or discontinued, tonics should be prescribed.
6. Little advantage can be anticipated from the employment of diuretics in those dropsies which originate from organic affections of the liver or the chylipoietic viscera, and still less in encysted dropsy. It is only in those cases connected with debility and deranged action of the capillary system, that diuretics can be regarded as certain remedial agents.

A. T. THOMSON.

**DROPSY.** (From the Greek, *ὑδρῶψ* — Latin, *hydrops*: — Th. *ὑδωρ*, water, and *ᾠψ*, the look or aspect.) Dropsy is a common term signifying effusion into the cellular tissue, or into any of the natural cavities of the body. With the addition of the epithet *encysted*, it has likewise been employed to designate a very different series of affections, viz., those collections of serous fluids which are contained in factitious sacs, and of which the ovary is more peculiarly the subject. These, as having neither the same origin, nor admitting the same treatment, will be spoken of in a separate article.

Even real dropsies differ so much from each other, in consequence of the organs in whose neighbourhood or in whose substance they form, that they cannot all be comprehended in one article. Thus hydrocephalus, though agreeing in having as one of its terminations an effusion of serum into the ventricles of the brain, can by no means be regarded in the same light with effusion into the larger cavities of the body. Its progress is more rapid, its origin more decidedly inflammatory, and, when it assumes a chronic form, it never gives rise to anasarca, which almost constantly attends hydrothorax or ascites. Hence, therefore, under the common head of dropsy, we can only consider this and other local dropsies, so far as the same theoretical explanations of their phenomena agree with each other; and our chief

attention must be paid to the form, origin, and treatment of what is commonly denominated general dropsy. For the peculiar symptoms by which hydrocephalus, hydrothorax, and hydrops pericardii are indicated, we refer to the articles under which these affections are treated.

The ancients appear to have had very crude notions of the cause of dropsy, and any approach to a rational theory of the disease is of very modern origin. Hippocrates explained its occurrence by the corruption and softening of the flesh, and its conversion into water. Celsus states that the common cause of dropsies is too great an abundance of humours. Galen, attempting greater refinement, referred it to refrigeration of the liver, which he assumed might happen either from an affection of that organ itself, or from sympathy with other organs; and with little modification this theory of Galen was received in the schools till after the discovery of the lymphatics by Asellius.

Forestus, who wrote in the latter part of the sixteenth century, adopts the opinion of Celsus, and explains it by the theory of Galen. He assumes that in consequence of the refrigeration of the liver, the veins also become refrigerated: hence a more serous state of the blood and greater abundance of water; and hence, according as the affection is local or general, anasarca or ascites is produced.

Fernelius, apparently seeing the insufficiency of this theory, referred anasarca to refrigeration of the liver, and ascites to a rupture of the vessels which contained the humours. By these, however, it is scarcely possible that he could intend the lymphatic vessels, as he wrote before the discoveries of Asellius had been published, and long before these vessels were supposed to be so general as it is now known that they are.

Sennertus, following Fernelius, made a somewhat nearer approach to a rational theory; for while he adopted the old doctrine with regard to anasarca, he attributed the occurrence of ascites to obstruction of the liver and spleen, by which means the vessels were distended with fluid, their extreme mouths dilated, and an escape of serum permitted into the cavity of the abdomen. The discoveries of Asellius gave rise to a different theory, and dropsy was referred to a rupture of the lymphatics. Judging from the language of Lower, it might be supposed that this doctrine had obtained considerable support, when the well-known experiments of this physiologist laid the foundation for a more rational explanation of the phenomena of effusion than any which had yet been given. By tying first the inferior cava, and afterwards the jugular veins, he did much more than any of his predecessors—he *proved* that effusion might be caused by obstruction in the veins. Neither Sydenham, nor Mead, nor Willis appear to have concerned themselves much with the theory of dropsical effusions, but were content with simply inculcating particular modes of practice. Soon after Mead, or even while he was yet living, Haller was laying the foundation for more rational explanations of the phenomena of dropsy. He adopted the then general theory of absorption by the veins, and lays down distinctly that dropsy may ensue, not only when the veins are obstructed,

but when the course of the blood through the veins is retarded by debility, whatever may be its source.\*

Haller did not acknowledge the absorbing office of the lymphatics, but even when, in consequence of Dr. Hunter's doctrines, absorption was entirely referred to those vessels, it made no difference in the theory of dropsical effusions. It was only necessary to change "veins" into "lymphatics," and it was supposed that a sufficient explanation had been given.

Such is a short outline of the attempts which have been made to explain the phenomena of dropsy; and at the beginning of the present century the general opinion seems to have been that the disease depended upon defective absorption, and that it was essentially a disease of debility. The investigations of various writers into the causes and treatment of hydrocephalus, which served clearly to prove that this disorder had very frequently an inflammatory origin, naturally tended to re-open the general question; and Blackall, Abercrombie, and many others were led to teach that both anasarca and ascites are often attended with and dependent upon inflammation. Former writers had indeed given examples of dropsies successfully treated by bloodletting; but these for the most part were single cases; and no attempt to lay down any general plan had been made till the time of the writers just referred to. Multiplied experience has now determined the question of treatment; and that in many cases an antiphlogistic plan is requisite, is no longer a matter of doubt. But whether dropsy depends upon increased exhalation or diminished absorption, is yet undecided; nor do we feel that the facts are sufficiently numerous to determine the dispute. We shall shortly give the principal arguments for either theory.

That dropsy proceeds from deficient absorption is argued, because, whether we consider the veins or lymphatics the instruments of this function, pressure upon their trunks is followed by an effusion of serum into the parts farthest removed from the heart. This, indeed, till some late experiments by Magendie, was the only real fact which could be adduced in favour of diminished absorption. This physiologist, by inducing an artificial plethora, and then showing that the function in question was less actively exercised than in those cases where no such plethora existed, has certainly given additional probability to the theory, and, under any circumstances, has proved what before was purely hypothetical—that absorption is capable of being diminished. On the other hand, that increased exhalation is the cause, is argued from the circumstance that absorption actually proceeds in dropsy, that the fat is taken away, and that emaciation advances *pari passu* with the effusion; that this function is always the last to yield, and that it appears to become more energetic in proportion to the general debility of the system; that the exhalents are capable of pouring out very dif-

\* Sed etiam absque ejusmodi causis hydrops nasci videtur, quoties debilitas aliqua, undecunque nata, iter venosum tardat. Facile enim intelligitur, in universum duntius sanguinis per arterias motum superesse, quem cor proximum terget, priorem vero motum venarum quiescere. Ergo si arteria exhalare pergant, venæ resorbere cessant, collectus vapor in hydropem abit.

ferent quantities of fluid, as is seen in the secretion of tears, the sudden increase of perspiration, &c.; and, lastly, that the fluids effused are different from the natural secretions of the parts, containing a much greater quantity of serum; and that this difference would not exist if dropsy were the simple result of diminished absorption.

A far more important question, however, to the practical physician, is the condition of the system under which effusion takes place—whether it be a sthenic or asthenic state. Whether we adopt increased exhalation or diminished absorption as the source of effusion, this question will admit of the same decision. Effusion may clearly take place in a state of debility and in a state of undue activity of the system, or of plethora. With regard to absorption, the experiments of Magendie have clearly proved that plethora is unfavourable to this function; and that it is favourable to increased exhalation, the profuse perspirations of persons having a full habit clearly evince. If such individuals are bled, the tendency to perspiration either yields entirely or is greatly diminished.

We have therefore to investigate carefully, in every case of dropsical effusion, the general state of the system by which it is accompanied, for what may be proper for one state will most undoubtedly be injurious to the other.

The only points, then, that we can assert as proved in the theory of dropsy, are—first, that the balance between exhalation and absorption is broken, in consequence of which more fluid is poured out than is taken away; and, secondly, that this may take place from over-activity or from debility of the general system.

Something may attach also to the condition of the blood, but upon this point we have very little satisfactory information. That hemorrhages increase the serous portion of the blood, and that profuse hemorrhage gives rise to dropsy, is certain; and that in dropsies, more especially those accompanied with extreme debility, the blood often exhibits a remarkable difference in the proportions of serum and fibrine, in its coagulability and in its colour, is likewise certain; but we have yet no data by which to connect these phenomena with dropsy as cause and effect.

Almost the only information, till the late advancement of chemistry, which had been obtained respecting the nature of the fluids effused in dropsy, regarded the colour and taste, although in a few instances the consistency and coagulability had been noticed. They have been described as a yellowish serum, as being of the colour of urine, orange-coloured, saponaceous, purulent, bloody; and, in one instance, Morgagni observed the fluid to coagulate without heat. For a more particular account of these fluids we are indebted to Marcet. He examined them in hydrocephalus, ascites, hydrothorax, and in most other dropsies; and he has given a detailed account of the result in the second volume of the *Medico-Chirurgical Transactions*. According to this statement, the prevailing animal substance is albumen, which is contained in very different proportions. There is also a peculiar animal substance which Dr. Marcet names muco-extractive matter, from its being uncoagulable, but soluble in water and other men-

strua. Gelatine was not discovered in any of these fluids.

In the fluids of ascites, hydrothorax, hydrops pericardii, hydrocele, and that which is sometimes effused in the thyroid gland, the albumen is so considerable as to render them coagulable; while in that of spina bifida and hydrocephalus, it is so small in quantity as scarcely to be rendered visible by heat or acids. The specific gravity is exceedingly various both in different dropsies, and in the same dropsy at different periods.

These differences, however, are found to affect principally, if not exclusively, the animal matter only of dropsical fluids; the saline matters being by no means subject to similar variations.

The particular saline ingredients of all these fluids are muriates of soda and potash, sulphate of potash, soda and phosphate of lime, iron, and magnesia. A hundred grains appear to consist of about seventy-two grains of muriate of soda, mixed with a little muriate of potash; between eighteen and twenty grains of soda, brought to the state of subcarbonate; and a mixture of eight or ten grains of sulphate of potash, phosphate of lime, phosphate of iron, and phosphate of magnesia.

The caustic alkali contained in these fluids, Dr. Marcet proceeds to say, appears to be combined with the animal matter in a manner not well understood, and the proportion of the uncombined alkali to the other salts is greater as the specific gravity is more considerable. To this account of the animal fluids Dr. Marcet has subjoined the following table, to show the proportions of saline and animal matter in various dropsical or serous fluids, and in the serum of the blood.

	Sp. Gr.	Total of Solid Contents.	Quantity of Animal Matter.	Quantity of Saline Matter.
Fluid of spina bifida	1007	14.4	2.2	9.2
Hydrocephalus	1006.7	9.2	1.12	8.08
Ascites	1015	33.5	25.1	8.4
Ovarian dropsy	1020.2			8.0
Hydrothorax	1012.1	26.6	18.8	7.8
Hydrops pericardii	1014.3	33	25.5	7.5
Hydrocele	1026.3	80	71.5	8.5
Blister	1024.1			8.1
Serum of blood	1029.5	100	90.8	9.2

The specific gravity here stated is an average.

I. Dropsies may be acute or chronic, idiopathic or symptomatic, primary or secondary, general or local, inflammatory, sthenic, asthenic, &c. These varieties occur in every cavity in which dropsy itself takes place, but the different forms are more common in one cavity than in another. Thus, the brain is most frequently the subject of acute dropsy; the pleuræ and pericardium hold the next place in this liability to acute effusions, and the peritoneum the last. The cellular texture is perhaps on an equality in this respect with the pleura and pericardium, but it is seldom affected without some organ suffering at the same time, in whose action it participates. Dropsy of the sthenic character is for the most part an acute, but not always an inflammatory disease. It chiefly assumes the form of anasarca. (See ANASARCA.) Sometimes it appears to be purely idiopathic, and unattended by disease or affection of any particular organ

In this case the anasarca takes place very suddenly, the whole cellular tissue sometimes becoming in a few hours enormously distended with fluid; and there is considerable heat of skin, with a full and hard pulse, furred tongue, and much thirst. Not unfrequently the patient complains of tenderness over almost the whole surface of the body, especially if strong pressure be made, so that we might be induced to believe that the cellular tissue under these circumstances is in a state of inflammation. The bowels are generally costive; the urine coagulates on boiling, the precipitate thus formed being very various in quantity,—sometimes scarcely rendering the urine at all muddy, at others forming almost a solid mass. This state of the urine, it has been inferred, is conclusive of disease in the kidney;\* but we shall in the course of this article afford reason for questioning this inference: it certainly indicates a disordered function of this organ, and not unfrequently accompanies structural disease of it.

Much more frequently acute dropsy is accompanied by inflammation of the lungs or pleura, and sometimes of both. The pulmonary symptoms, however, are not always very prominent, and they sometimes nearly disappear when the effusion has taken place. In such cases, inquiry into the history of the patients generally shows that they had suffered for several days, or occasionally several weeks, from cough and dyspnea, and that about the period at which these symptoms diminished in severity, the face was perceived to swell in the morning and the legs at night, and the abdomen, without being very perceptibly enlarged, would not allow the clothes to be buttoned or laced so tight as usual. From this time the swellings increase rapidly; the whole cellular tissue becomes affected, and the countenance is very leucophlegmatic in appearance. At other times the pulmonary symptoms and effusion proceed *pari passu*, or the former precedes the dropsy only by a few hours, but is not relieved by the occurrence of effusion.

The progress now described is generally exhibited in the acute anasarca, from whatever source it may have derived its origin; but not very seldom effusion takes place to a considerable extent into the abdomen at the same time, and the ascites quickly becomes equally marked, if not the more prominent symptom.

Ascites is much less frequently an acute disease than anasarca, and in most cases is the result of previous inflammation. In the article ASCITES we have described several instances of this kind.

The exciting causes of acute dropsy are,—the repression of eruptions, the sudden suppression of perspiration, suspension of the catamenia, or of any other customary evacuation, inflammation of the lungs and pleura, exposure to cold, &c. It also succeeds scarlet fever, when this disease has run its regular course; sometimes it has succeeded parturition, coming on suddenly and without any pain. In this last case, ascites alone is often observed; but at other times it is accompanied by excessive anasarca. The ascites succeeding parturition is also at times very manifestly dependent upon peritoneal inflammation, and is

attended with fever, quick, small, wiry pulse, and excessive tenderness of the abdomen, &c. These symptoms precede the effusion, and the tenderness diminishes, but does not entirely disappear upon its occurrence. In some of these cases, when the abdomen has been emptied, we have discovered an enlarged ovary, and we are inclined to believe that it is to the irritation produced by disease of this organ, with the additional stimulus of the puerperal state, that the effusion is owing. The termination of such cases is various: in some, after the disappearance of the dropsy, the tumour remains quiescent, and is not attended by any inconvenience; in others the ascites, indeed, is removed, but the ovary continues to enlarge, and we have at length encysted substituted for peritoneal dropsy.

Dropsy may be acute as to the rapidity of its formation, and yet be the very reverse of an inflammatory disease. This variety is, however, much more rare than the preceding species, but, like it, assumes the form of anasarca or of ascites alone, or of both together. It comes on in general very rapidly, and is unattended by fever or any symptom of increased arterial action. In the article ANASARCA an instance has been mentioned, taken from Dr. Bateman's reports of Diseases in London, where it came on after excessive fright, and was removed by the administration of cinchona. In the form of ascites we have several times seen it follow parturition; the patient being, within a few days of delivery, as large or even larger than at the period of labour. In these instances the only striking symptom is debility; there is neither thirst, nor heat of skin, nor quickened pulse; and the patient appears to suffer no other inconvenience from the effusion than what proceeds from the increase of her bulk. The progress of such cases towards recovery is very slow, and is always impeded by violent depleting remedies. The most successful plan of treating this affection is generally by slight tonics, frictions over the bowels, and bandaging. It ought, however, to be remembered that such patients are liable to become the subject of sub-acute inflammation; and unless great watchfulness be practised, the disease from this cause may become incurable.

Of the same asthenic character are those forms of effusion which are the consequence of any excessive discharge, and more especially hemorrhage. We have mentioned one instance in the article ANASARCA in which the hemorrhage was the consequence of diseased uterus; and the anasarca (the form such dropsies generally assume) appeared and disappeared, as the hemorrhage prevailed or was suspended. Any other debilitating discharge will unquestionably lead to similar results.

II. We shall now proceed to notice those species of effusion which are always the result of some organic disease, and which may therefore be termed symptomatic or secondary dropsies. They are usually chronic in their course, are seldom attended with acute inflammation, but very frequently accompanied with sub-acute inflammation.

**Dropsy from Disease of the Heart.**—*[Cardiac Dropsy.]*—This species of effusion is

Dr. Bright, however, to whom this notion owes its origin, by no means carries this doctrine so far.

usually preceded by the common symptoms of disease of this organ, and such disease may precede, and often does precede, the occurrence of dropsy for months, and even for years.

The first symptom of dropsy arising from disease of the heart is usually observed in the face, the eyelids being puffed in the morning, and an unusual difficulty of opening them being experienced. This single symptom frequently endures for a very considerable time before any farther progress is observed. Next, the feet swell at night, and the upper extremities become very quickly the site of effusion, and the left arm earlier and more frequently than the right.

The anasarcaous swelling, which is peculiarly pellucid, usually long precedes the occurrence of ascites; effusion taking place in the peritoneal cavity late in the disease and very slowly. Frequently, indeed, patients are examined, in whom anasarca has been the consequence of cardiac disease, without a single ounce of fluid being found in the abdomen; and sometimes, although more rarely, not even in the cavities of the pleuræ. The pulse is not always characteristic of disease of the heart; and of course the same difficulty must naturally occur in detecting such disease, whether accompanied or not accompanied by dropsy. When, however, effusion begins after long disease, and without pulmonary symptoms, in the face and upper extremities, we may always suspect the heart to be the source of the effusion. In many patients, and particularly in women, this first symptom appears to be followed by partial effusion into the chest, and for some weeks before any farther progress is made, the patient is unable to lie down. At first this difficulty of preserving a reclining posture is very slight, and only an additional pillow is required, the patient at this time being scarcely sensible that the inability of lying down is the consequence of disease. Gradually, however, the effusion increases, progressively involving every part of the system—the cellular texture and the cavities of the brain, pleuræ, and peritoneum.

The urine in some of these cases at a very early period affords a very slight deposit of albumen upon boiling, and this albuminous secretion becomes more and more abundant in the progress of the disease. Its quantity varies considerably. In a patient who died in the Birmingham Hospital during the present year at a very early stage of the effusion, two months before his death the urine was barely rendered turbid, but the evening he died it was rendered nearly solid, by boiling. On dissection, the heart was found enormously enlarged, and the aorta very much diseased. The kidneys were perfectly sound. The urine, however, does not coagulate in every case of dropsy arising from disease of the heart, nor is it very easy to say what is the precise state of the system in which this phenomenon does occur.

None of the species of dropsy is more frequently relieved, or we may say for a time even cured, than this; but it very frequently recurs, and at length, favoured by the exhaustion from long disease, and sometimes perhaps even by the remedies that have been necessarily employed, a very copious effusion takes place into the chest, and death often at last occurs very suddenly. Some-

times, and this is no unusual occurrence, the anasarca permanently disappears for some time before death, or remains but in a very slight degree. The oppression of the chest, however, is not diminished, and occasionally a greater determination of blood takes place to the lungs, or these organs become congested, especially if much obstruction occurs in the valvular structure of the left side of the heart. At this period hæmoptysis, acute pneumonia, and pleurisy, are very liable to ensue, and require the most decided antiphlogistic treatment. Even this treatment does no more than afford temporary relief, and inflammation occurs again and again, till the means of the physician are exhausted. To stimulate increases the inflammation, and farther depletion is rendered impossible by the extreme debility of the patient.

The course now described is not peculiar to any one affection of the heart; the symptoms are, more or less, the same under every malady of that organ. Some difference nevertheless exists according as the heart is the subject of what Corvisart calls active or passive aneurism; congestion and inflammation being more common in the former affection than in the latter. Often, indeed, when passive aneurism exists, advantage is derived from the lighter tonics united with diuretics, but active depletion is neither called for nor admissible: it reduces the patient without benefiting him as regards the disease.

#### **Dropsy from Disease of the Lungs.—**

Under the head of ANASARCA we have given several instances of this affection, when arising from or connected with inflammation of the lungs. For the phenomena attending it under such circumstances, we refer therefore to that article. It is not, however, only after inflammation of the parenchymatous structure of these organs that effusion occurs; it arises also after chronic bronchitis; after chronic pleurisy; and frequently, perhaps generally, in a greater or less degree, in the latter stages of tubercular phthisis.

The phenomena of dropsy, when arising from chronic bronchitis, do not materially differ, excepting as to the rapidity of its progress, from a similar affection after inflammation of the lungs. The face and upper extremities are in both cases the first to become œdematous. Sometimes this œdema is so slight, that it produces only slight stiffness at first waking in the morning, and is scarcely—occasionally not at all—recognised by the patient as the consequence of any swelling of the eyelids. At a shorter or later period after this, the ankles swell, and the affection in this stage may remain nearly stationary for months and even for years. As, however, chronic bronchitis is liable to pass at particular periods into a sub-acute, sometimes even into an acute form, there is usually at the same time an increase in the effusion, which will thus be found to increase and subside with every aggravation or alleviation of the original malady. We have in this manner known an individual pass seven or eight years without any material alteration; in the summer enjoying a tolerable state of health, in the winter threatened with a fatal termination from fresh attacks. It ought also to be observed, that each attack leaves the individual in a less favourable state than before. At length the dropsical effusion begins to increase

more rapidly; the whole cellular texture becomes anasarcaous; fluid is poured out into the cavities of the peritoncum, the chest, and the brain, and death ensues from the affection of one of these latter cavities. Sometimes the pleuræ, the pericardium, and the cellular texture of the lungs become so dropsical, that the patient is unable to lie down, and at last appears to die from suffocation; and not unfrequently death takes place very suddenly under such circumstances. Another termination is in effusion into the ventricles of the brain, and the patient dies with the common symptoms of apoplexy, or falls into a doze, and imperceptibly passes from a state of sleep to actual death.

To this general description of the course which dropsy from chronic bronchitis pursues, is to be added, the supervention of fresh symptoms as additional organs become involved. Thus palpitation of the heart supervenes with the effusion of fluid into the pericardium; the dyspnœa increases with the increase of effusion into the pleuræ or the cellular tissue of the lungs; the digestive organs become more disturbed as their functions are interfered with by the pressure of fluid within the cavity of the peritoneum; and if the brain is involved in the general disposition to dropsy, stupor, paralysis, or apoplexy, may and not unfrequently does ensue.

Dropsy likewise takes place in the latter stages of chronic pleurisy and tubercular phthisis, but it is not often a very prominent affection, and is chiefly confined to the lower extremities. Sometimes, however, the body becomes universally anasarcaous, especially in phthisis,—and very little can be effected for the effusion under such hopeless circumstances.

**Dropsy from Disease of the Liver, [Hepatic Dropsy].**—This species of dropsy has been recognized from the very earliest periods of medicine of which any record remains, and to this most of the older histories of dropsy refer. The form which it assumes is chiefly that of ascites; and some peculiar symptoms attend its progress, which deserve consideration in its treatment. Dropsy takes place in the latter stages of most hepatic diseases; nor are we acquainted with any mode of detecting the precise nature of such diseases during life,—whether there is nutmeg liver, or simple enlargement of it, or tubercular disease,—excepting in the last instance, when the bulk of the organ has so far increased that a tolerably correct opinion may be formed by external examination.

Disease of the liver usually exists for a long time before effusion takes place, and its earliest symptoms are little more than those of simple functional dyspepsia. There is flatulence, uneasiness at the stomach after eating, and often some pain and tenderness in the right hypochondrium; and occasionally at a very early period the lower edge of this organ may be perceived harder, larger, and lower in the abdomen than is usual. There is a short dry cough occurring at times throughout the day, but more particularly on first rising in the morning, and the sputa are blackish and occasionally dotted with blood. The pain passes sometimes backwards under the blade-bone; at other times the muscles covering this bone, with

the deltoid, become the seat of pain greatly resembling rheumatism, and not unfrequently mistaken for it. The urine is very red and deposits lithic acid, and the evacuations are usually, but not invariably, clay-coloured. In many instances sickness also is present, and a greater or less degree of jaundice. When this last symptom is united with those above enumerated, no doubt can remain that the liver is the seat of some important disease.

When the symptoms now mentioned have continued for some time, the ankles are perceived to swell at night a little, and the abdomen becomes somewhat fuller. The urine at the same time diminishes in quantity, the skin becomes dry and harsh, and the patient suffers from distressing thirst. The progress of the effusion from this period is very various; in some cases ascites is quickly formed, and the lower extremities become anasarcaous throughout; in others the ascites is complete, while there is scarcely any œdema present; and in a third series of cases, the progress of both is very slow: in these last the ankles remain long slightly œdematous without any increase of effusion, and sometimes for two or three weeks together it entirely disappears, so that the patient fancies that the dropsical tendency is gone; again however it returns, and the dropsy becomes permanent. The duration of the disease is likewise various; for while in most cases several months elapse from the commencement of effusion till the death of the patient, in others the effusion takes place only a few days, or two or three weeks before death; and we have sometimes seen the abdomen become excessively distended three or four days only preceding dissolution.

As in dropsy from disease of the lungs, fresh symptoms are added as additional cavities become the seat of effusion; but neither the chest nor the ventricles of the brain so readily pour out fluid as when the dropsy commences with an affection of the heart or of the lungs. The dyspnœa which usually comes on in the latter stages of hepatic ascites, is chiefly to be referred to the protrusion of the diaphragm into the cavity of the chest, and it is seldom that any cerebral disturbance exists in these cases. Generally, indeed, hepatic patients preserve their intellectual powers to the last in a very extraordinary manner. We have sometimes however seen delirium come on in a few hours, or a day or two before death; but this is so usual in the closing scene of all chronic diseases, that it cannot be regarded as an essential part of the affection we are now describing. Under these circumstances the patient gradually wastes away; and death seems the natural result of a debility that had been continually increasing till the moment of dissolution.

**Dropsy from Disease of the Spleen and Pancreas.**—There are no general symptoms by which we can readily recognise these organs as the sources of effusion. With regard to the spleen, its enlargement usually long precedes the occurrence of dropsy; and the diagnosis, consequently, when the patient is seen early, can seldom be difficult. Dropsy from this cause often disappears; and we have known in one instance the effusion and the tumour vanish together, after

the latter had existed for many months. The pancreas has not been much observed in dropsy, and we are not acquainted with any case of effusion that could be attributed to an affection of this organ.

**Dropsy from Disease of the Kidneys** [*Renal Dropsy*].—Many affections of these organs are capable of inducing effusion, and this is a common consequence when from any cause they are extensively diseased. The kidney is occasionally converted into a scrofulous mass; and we have met with cases, and several others are recorded, in which under such circumstances it formed a prominent tumour in the abdomen. A much less degree of disease is, however, sufficient to produce effusion. The form of dropsy under these circumstances is anasarca, and ascites does not usually take place till later in the disease. The œdema commences in the lower extremities, and in some instances which have come under our notice, the limb corresponding with the diseased kidney, where only one was affected, has swelled most; so that we are induced to believe that œdema in such cases is sometimes the consequence of pressure upon the ascending cava, or at least is aggravated by this pressure.

Dr. Bright has within these few years brought to the consideration of the medical world a peculiar change in the structure of the kidney, which he regards as the cause of dropsy, and the tendency to which change, or its actual occurrence, is indicated by the coagulability of the urine—[*Albuminuria*. (See KIDNEY, DISEASES OF THE)]. In these views he is joined by Drs. Christison and Gregory, the latter of whom has however shown that the peculiar alterations alluded to by Dr. Bright, and the presence of coagulable urine, often occur without dropsy. The peculiar nature of this change we shall intimate when we describe the morbid anatomy of dropsy.

Three forms of dropsy connected with disease of the kidney may be particularly traced in the cases recorded by the above-mentioned physicians:—the first commencing evidently with the respiratory or circulating organs, and united, either from the beginning or as the effusion proceeds, with disease of the kidney; the second, commencing with disease of the kidney, and secondarily affecting respiration and circulation; and a third in which the kidney is the only organ affected throughout. The first species differs little from that which we have already spoken of under the head of dropsy from disease of the lungs, excepting in the supervention of symptoms indicative of renal disease. These symptoms are sickness, vomiting, purging, pain in the loins, often united with coagulable urine; but this last may exist in a very great degree, and for a very long time, without any appreciable alteration in the structure of the kidney. The former symptoms exist in very various degrees, either alone or united, and are sometimes altogether absent.

The second form begins with anasarca only, which quickly becomes universal, and in a longer or shorter time, commonly within a few days, symptoms of inflammation of the lungs or pleuræ, or of both, supervene; and though this may be removed by appropriate treatment, it returns again, each time increasing the disorganization of these

organs, and sometimes also extending to the pericardium, and giving rise to adhesions between its surfaces. The dropsy also is, at the commencement of the disease, often easily removable, but still it returns, till at length a few weeks or days before death it disappears altogether. In these cases, it is frequently only the anasarca and ascites that disappear, and the cavities of the chest are found after death to be full of effused fluid. In this as in anasarca from other causes, effusion may take place in the brain; and knowing the sympathy between the kidney and this organ, it is by no means surprising that this is no unusual occurrence.

The third is a much rarer occurrence than the two former. Dr. Bright has given one instance of this, in which no other symptom was present than extensive anasarca with coagulable urine, containing a considerable quantity of the red particles of the blood. The anasarca disappeared under the treatment which was adopted, but the patient died suddenly from inflammation and œdema of the glottis. Dissection appears to have proved that in this instance the kidney was in a state of excessive congestion, if we may not go so far as to call it inflammation.

A peculiarity in patients suffering under this dropsy is their extreme liability to be affected by calomel. Dr. Bright and Dr. Gregory have related instances illustrative of their proneness to severe salivation from very small quantities of mercury, and we have ourselves witnessed cases of the same kind.

Much importance is attached by Dr. Bright and the Edinburgh physicians to the coagulability of the urine, as indicating extensive change in the structure of the kidney,—much more, indeed, than it appears to us the evidence afforded is able to sustain. Dr. Wells has long ago shown that this symptom appeared and disappeared under circumstances in which it could not fairly be regarded as the consequence of organic disease. He saw it suddenly induced by the exhibition of mercury: he knew an individual in whom it appeared probable that the coagulability of the urine had existed for nine years: he also pointed out the frequency of its occurrence in that form of dropsy which succeeds scarlatina; and showed, likewise, that with the disappearance of the dropsy the kidneys ceased to pour out serum. Dr. Bright himself contends only for functional disease in the first instance, leading secondarily as in other cases to organic disease; although it must be confessed, from the great stress which he lays upon this one symptom, a cursory reader might easily mistake his meaning. Dr. Elliotson, also, is reported to maintain that the urine may strongly coagulate for a time without any change in the structure of the kidney.

We are, however, disposed to go even farther than this; and without denying that in some instances coagulable urine is the consequence of serious primary disease in the kidney, nevertheless to maintain,—that in many instances it is merely a symptom very remotely connected with organic alteration in the kidneys. As a secreting organ, the kidney is especially liable to be affected by the pabulum afforded it; and should the blood reach it in an imperfect state, whether in consequence

of indigestion, imperfect change in the lungs, or inordinate action of the heart, or insufficient nervous influence, we may expect that its function will be impaired. Accordingly we see it deposit yellowish sediments in indigestion, laceritious sediments in febrile diseases, and, phosphates after injury of the spine. Now in very many of the cases, perhaps in the majority, of dropsy with coagulable urine, the effusion is preceded by inflammatory symptoms of the organs of respiration; and in many there is disease of the heart. Considering the important changes that take place in the blood during its passage through the lungs, we can hardly be surprised that an affection of these organs should influence the secretion of urine; and again, while apoplexy is distinctly traceable to hypertrophy of the heart in some cases, it surely is not extraordinary that by this organ also the secretion of the urine should be modified. But we are not left only to theory on this point: the numerous cases in which the urine coagulates, already referred to, and in which organic disease cannot fairly be presumed to exist, confirm to a certain extent this view of the subject, while morbid anatomy still farther corroborates it. In two instances which we have lately had an opportunity of examining, where the urine had strongly coagulated during life, no disease whatever was observable in the kidney. To one of these we have already referred. The other occurred in a lady who had been suffering from pulmonary symptoms, and symptoms of disease of the heart, for nine months, when we first saw her. At this time the urine coagulated strongly, and continued to do so till the period of her death, three months afterwards. Yet, while the left lung, the pleura, and the heart, exhibited serious disease of long standing, and while the liver was also diseased, though in a slighter degree,—there was no appreciable change whatever in the substance of the kidneys. A small cyst containing a colourless fluid was seated on the superior convex portion of the left kidney, but did not in the slightest degree interfere with its structure. In this case there had never been any pain in the back.

The view we now contend for is by no means unimportant as a guide to practice; for the plan of treatment must necessarily be different, according as we consider the kidney primarily or secondarily affected. Should we find reason to believe that the respiratory organs are the earliest and principal sufferers, our chief attention must be paid to them. As a guide also to a correct prognosis, this view is most important; because, if the kidney is to be regarded as organically diseased in every case of coagulable urine, all such cases would be evidently hopeless, and little would remain for the physician but to smooth the path to a fatal termination.

The next question which presents itself connected with this state of the urine, is the condition of the system in which it exists. Dr. Blackall regarded it as inflammatory; Dr. Prout regarded it rather as proceeding from irritation than inflammation, (Prout on the Urinary Organs, first edit. p. 48); and other authors appear to have paid scarcely any attention to this part of the subject, excepting so far as stating that it could not be relied upon as a guide in practice. That it is at

times connected with an inflammatory state of the kidneys, the following case, which occurred in our practice several years ago, abundantly proves.

A girl, twenty-three years of age, applied on the 11th of July, 1823, complaining of severe pain across the back, in the region of the kidneys, with shivering and frequent sickness. A short time before, the right foot had swelled; but at the time of her application this had subsided. Her urine was of a dark brown colour, depositing a thick precipitate upon the addition of tartarized antimony, and becoming of the consistency of melted butter by boiling. She made water very frequently, but very little at a time. She complained of pain in the pudenda. The catamenia were scanty, but regular to the period. She had had scarlet fever six months before, and her urine had been of the dark colour, now mentioned, ever since, but occasionally becoming a little clearer. This case was regarded as inflammation of the kidneys, and treated accordingly, and on the 21st of July, she was convalescent; the urine had then returned to a healthy state, being lighter in colour, and affording no coagulum upon boiling. On the other hand Dr. Blackall has given a case of dropsy after scarlatina, in which the urine remained coagulable after the effusion had disappeared, and regained a healthy state under the administration of cinchona. At the present time we have a case of dropsy with coagulable urine, in which the quantity of serum greatly diminished for a few days after taking sulphate of quinine.\* Dr. Bright also remarks that occasionally we find anasarca even with coagulable urine so marked by debility that tonics and steel give decided relief.

Dr. Wells has seen the urine become coagulable after the exhibition of mercury, and this is now a well-known effect of mercury. Dr. Bostock observes that in a great majority of cases of persons in apparent health, serum may be detected in the urine by the appropriate tests, and that in his own person he had observed it to be increased to a considerable amount by the slightest causes. In a patient of the Birmingham Hospital, who had had anasarca connected with bronchitis, after both diseases had disappeared, and the urine, which had originally been coagulable, had recovered its healthy condition, it was found one day immediately after dinner to be rendered almost solid by heat, and the next morning the same means did not detect a single particle.

These few facts abundantly confirm the opinion of Dr. Prout, that taken alone "as a symptom, the albuminous urine does not, in the present state

\* The patient here alluded to was in the Birmingham Hospital, and died soon after the above was written. The body was examined, but there was no alteration in the structure of the kidneys. The cortical part was paler than usual, but retained its natural structure, and the tubuli were perfectly distinct. The kidneys were exhibited to several of the medical officers of the establishment, who all agreed that there was no change whatever of structure. The liver in this case was, if anything, smaller than natural, and externally had exactly the appearance of lung; internally it appeared as if it were pervaded by inspissated bile, and was firmer than natural. The peritoneal coat had contracted numerous adhesions with the diaphragm. The heart was remarkably small, the walls of the right cavity were very thin, while those of the left compared with the right were enormously thick. These were the only unusual appearances about the body. This man had been a spirit-drinker.

of our knowledge, indicate the use of any particular remedy or mode of treatment; but that, nevertheless, it is a symptom of which we ought always to be aware, since, taken in conjunction with the others, it may be occasionally useful in directing us to form a more correct judgment of the general nature of the disease."

Albuminous urine appears to be much more intimately connected with anasarca than with ascites. Dr. Wells found it, in twenty-four cases out of thirty-seven, connected with anasarca; in fourteen cases of ascites previous to anasarca, there was no scrum in the urine; and in eight cases of anasarca subsequent to ascites, the urine in all contained serum, and in one it was rendered solid by heat. Of the seven cases related by Dr. Christison, anasarca was the principal form of dropsy in six, and in the seventh only was the ascites a prominent symptom. Much the same proportion is observable in Dr. Gregory's cases; and in the twenty-three cases recorded by Dr. Bright, anasarca was the form of effusion in all.

We cannot dismiss this part of the subject without some observations on the composition of coagulable urine. Dr. Bright believed that the dark brown colour was frequently owing to the presence of the red globules of the blood, and in this opinion he is supported by Dr. Gregory. The case of inflammation which we have already given strongly supports this view, and there are few physicians probably who will doubt the possibility of its occurrence. This point therefore we may now leave: a much more important part remains, viz. to afford our readers the best means of investigating some of these points themselves.

All the writers referred to (and in numerous instances we have confirmed the fact by our own experience) state that coagulable urine has a much less specific gravity than healthy urine; and Dr. Gregory has given two tables containing the result of an equal number of trials with coagulable and with healthy urine. The average specific gravity in fifty cases was in healthy urine 1022.46, the highest being 1033, and the lowest 1005; while in the coagulable urine, the highest was 1023.5, and the lowest 1006.5.

With regard to the best means of detecting albumen when it exists in urine, we may observe that heat, while it is of readiest application, will generally be found sufficient. It is often advisable, however, to make use of re-agents, and of these corrosive sublimate is the most delicate. The nitric and muriatic acids are also employed for the same purpose, as is also the ferro-prussiate of potash, and alcohol. With respect to the effects of these latter re-agents, Drs. Gregory and Bostock are somewhat at issue. The former says that he never knew a case in which they caused a precipitate when heat had no effect, while Dr. Bostock observes, "I have also found certain states of the urine where heat had no effect, but where muriatic acid threw down a precipitate, and again where muriatic acid had no effect, but where the albumen was detected by the bichloride of mercury, or the ferro-prussiate of potash." All, therefore, that can be deduced is, that all these re-agents should be employed in succession in suspected urine, when the first fails to discover albumen.

**Dropsy from Disease of the Uterus and Ovaries.**—Many of the affections of the uterus, after they have existed long, give rise to dropsical effusions into the lower extremities. Sometimes this appears to be the result of pressure only upon the great vessels, when the uterus is either enlarged itself or contains a tumour of considerable size. At other times the effusion appears to be the result of the hemorrhage to which, under certain forms of disease, the uterus is peculiarly liable. This therefore is not fairly to be referred for its origin to organic disease of the uterus; the dropsy is simply the consequence of the hemorrhage, and hemorrhage from any other organ would give rise to similar results. With regard to the ovaries, we know that they are themselves the seat of those affections which are called encysted dropsies, and in this light they do not at present demand our consideration. But affections of the ovaries appear sometimes to produce real ascites, while they still present only the character of nearly solid tumours, and at the same time the lower extremities become cedematous. We have already mentioned our suspicion that ascites is sometimes a consequence of ovarian disease, subsequent to parturition, and we have met with cases of bronchitis in which ascites has taken place earlier than probably it would have done, had not ovarian disease existed previously.

**Morbid Anatomy.**—This naturally divides itself into two parts:—first, the morbid anatomy of the serous membranes and cellular tissue, which are the immediate sources of the effusion; and, secondly, the morbid changes of the various viscera, in consequence of which the serous membranes and the cellular tissue assume a dropsical disposition.

1. The most ordinary appearance in the serous membranes is thickening and opacity, which are more or less manifest in every serous membrane of the body. Thus in hydrocephalus, the lining of the ventricles, though seldom separable as a membrane, is evidently firmer and more condensed than natural; but the changes referred to are much more easily seen in the pleura, pericardium, and peritoneum. All these membranes become opaque or thickened; coagulable lymph is thrown out; and we not unfrequently find large layers of lymph converted into factitious membranes. Tacheron (*Recherches Anatomico-Pathologiques*, vol. iii. p. 196) says, "The pleura has been found thickened and covered with a layer of villous matter, oily to the touch, whitish, and similar to the intestines of the cow when converted into tripe." The same author has given an example of both pleura and the peritoneum becoming tuberculated. Dr. Ayre has related a case of ascites in which he found the peritoneum thickened and opaque, quite white, and having nearly the thickness of chamois leather. In the Quarterly Review of Foreign Medicine, a case is given of a woman who became dropsical after being brutally kicked by her husband: in thirteen years she was tapped 665 times, and on dissection the peritoneum was found cartilaginous and three lines thick.

So far as the serous membranes themselves are concerned, these appear to be the principal changes. With respect to the cellular tissue, Portal tells us that in dropsy it is more or less thickened, that

the cells are dilated, and many converted into one, and that he had seen the intermuscular cellular tissue put on a cartilaginous appearance under such circumstances. (*Portal, Des Hydropisies, tom. ii. p. 12.*)

Morgagni relates a case of anasarca in which the tissue was thickened, and, as he says, the fluid, from the frequent intervention of the cellular layers, assumed the likeness of gelatine. Bichat observes that in prolonged cases of leucophlegmasia, the subcutaneous fluid is by degrees infiltrated through the prolongation of the areolæ of the skin, separates their fibres, and sometimes penetrates to the epidermis, which it bursts in different places, and the fluid escapes through the apertures which are thus made. (*Bichat, Anatomie Générale, p. 689.*) In the case above referred to, from Morgagni, the cuticle had been thus raised, but not burst, so as to form immense bladders, which were filled with water. (*Morgagni, Ep. xxxviii. c. xxvi.*) The cellular tissue itself is in such cases remarkably bleached.

This is perhaps the proper place for noticing the changes which occur in the absorbent vessels and veins. It has been often assumed that the former may be dilated and burst, but we know no cases which afford confirmation to such an opinion. That the absorbent vessels are more easily detected in dropsical bodies is true, but this probably is chiefly owing to the removal of the adipose substance of the system. Dr. Hodgkin, however, has lately rendered it probable that these vessels are in some way connected with effusion. He has related several cases of dropsy in which the absorbent glands, and especially those surrounding the great vessels, were enlarged and indurated. (*Medical Gazette, January 21, 1832.*) This enlargement appears to consist throughout of a uniform texture, rather the consequence of a general increase of the whole gland, than a new structure displacing the original one. It is simply an hypertrophy therefore of the glandular system. In illustration of this morbid growth, five cases are given, two in children, one nine and one ten years old; one in a man aged thirty, and two in persons of fifty years of age. In four of these cases the spleen was enlarged; and a fifth case of enlarged spleen with general induration of the absorbent glands is referred to, drawings of which were made by Dr. Carswell, and are contained in his collection.

In local anasarca the veins frequently exhibit peculiar appearances. Sometimes their cavities are completely obstructed by fibrinous clots, which have evidently formed during life. In other cases the internal membrane is thickened, red, and covered with coagulable lymph. Occasionally pus is found in their cavities.

Diseases of the arteries are often found in dropsy, and particularly aneurisms of the aorta. The late Mr. Freer believed that inflammation of the lining membrane was common. We are not aware that this observation has been confirmed, but we have seldom opened a patient dying with general dropsy who did not exhibit some disease of this membrane. This generally consists of scrofulous or bony deposits, with frequent ulceration; and we once saw the descending aorta beset with nume-

rous incipient aneurisms, from this cause, a few of them being larger than a good sized pea.

2. The lungs are frequently found with the appearances consequent to bronchitis. The bronchial membrane is inflamed, and its texture thickened, sometimes even ulcerated. The cavities of the bronchi and air-cells are filled with a frothy fluid, and sometimes with pus. At other times we find the common results of pneumonia, congestion of the lungs, serous infiltration, hepatization, purulent infiltration, &c. When dropsy of the pleura has existed long, the lung is often so much compressed as to form a solid body, wholly or in part impervious to air.

Tubercles are not unusually discovered in dropsical patients, although no suspicion of tubercular phthisis may have existed during life.

The various organic alterations of the heart are also frequent in this disease, and may, doubtless, be regarded as the original cause of effusion. For a more minute account of these morbid changes we refer the reader to the articles on the diseases of this organ.

The liver exhibits an immense variety of appearances in dropsy. It is sometimes hard and scirrhus, many instances of which are given by Morgagni. (*Epist. xxxviii.*) Dr. Baillie says in many cases of ascites the liver is diseased, being hard and tuberculated; and in another place he has particularly described the kind of change which is here meant. The tubercles which are formed in this disease occupy the whole mass of the liver, are placed very near each other, and are of a roundish shape. They give an appearance everywhere of irregularity to its surface. When cut into, they are found to consist of a brownish or yellowish-white solid matter. They are sometimes of a very small size, so as not to be larger than the heads of large pins; but most frequently they are as large as small hard nuts, and sometimes larger. When the liver is thus tuberculated, it feels much harder to the touch than natural, and not uncommonly its lower edge is bent a little forwards. Its size, however, is not generally larger than in a healthy state, and sometimes Dr. Baillie thought it was smaller. If a section of the liver be made in this state, its vessels seem to have a smaller diameter than they have naturally; and it frequently happens that the liver is of a yellow colour from the bile being accumulated in its substance. The gall-bladder is generally contracted, and of a white colour, from its being empty. Dr. Baillie also mentions a peculiarly hard liver, which exhibits, when cut into, no peculiar structure, and is also accompanied by incipient ascites. This state of the liver has frequently fallen under our notice, and we have found it still only unusually firm when the ascites has been very considerable.

Dr. Bright has described an appearance of the liver, probably the more advanced stage of the last morbid structure, and which seems really to deserve the name of scirrhus. The substance of the liver is hardened throughout, and bands of thickened cellular membrane, like ligamentous matter, pervade every part: in some parts of the liver from which this description is drawn, it formed one-third of the whole structure. Although, when seen externally, the liver appeared tuberculous

and knotty, yet when examined internally there were no tubercles. The liver is also sometimes studded with large white tubercles; and we have seen the structure of the organ so completely obscured by their accumulation, that it could scarcely be recognised. This disease, however, seldom gives rise to effusion till it has made very extensive progress. The weight of the liver in such cases is often very great: in a patient whom we examined last year, it amounted to eleven pounds.

The changes now enumerated form indeed but a small part of the modifications to which this organ is liable, and which are found to give rise to effusion. The observation of Dr. Bright, however, that those changes in the structure of the liver by which the branches of the vena portæ are compressed more frequently give rise to dropsy than any of the circumscribed changes, (as tubercles of various kinds, and hydatids occurring imbedded in their substance,) is perfectly accordant with our own experience; and the observation we have just made respecting the period of effusion in tubercular disease of the organ, drawn as that observation is from numerous facts which have fallen under our notice, is an additional confirmation.

The colour of even what is called a healthy liver is exceedingly various, and hence, from colour alone, it is not easy to draw any positive conclusions. Sometimes, however, the variation is so decided that we cannot hesitate to pronounce the structure diseased. The most remarkable of these changes is that which has been termed the *nutmeg* liver, and this term more completely explains the appearance than any lengthened description can do. Sometimes the whole liver is much lighter than usual; at others it is yellow, and appears to be filled with inspissated bile; and Dr. Bostock has rendered it probable that this is actually the case, for in a liver of this kind submitted to his examination, he inferred from numerous experiments that it contained cholesterine, the substance which forms the basis of biliary calculi. In a liver which we examined within these few days, the colour externally was that of hepatized lung, and it might easily have been mistaken for this organ so far as the colour was concerned. The interior was very dark, yet we could scarcely say that the structure was diseased. [See LIVER, DISEASES OF THE.]

The spleen is also frequently found in a diseased state in dropsy. It is sometimes much harder than natural, and at the same time considerably enlarged. It will occasionally attain an enormous bulk, forming a very prominent tumour in the abdomen, and after continuing some time, giving rise to effusion, by which the tumid spleen is subsequently concealed. The structure of the spleen does not in such cases appear altered, but is only firmer and more compact, still retaining its natural colour and granulated appearance. Sometimes this organ is covered with small white cartilaginous bodies, probably tubercles, as we once found them in a man whose lungs were studded with similar particles; and Dr. Hodgkin has related a case in which they seem to have pervaded the substance of the organ. In this instance the spleen was at least nine inches long, five broad, and proportionably thick: its structure consisted of an

almost infinite number of small white globules, which appeared to arise from deposits in the cellular tissue of the organ.

The pancreas is seldom diseased in dropsy; we have sometimes thought it much harder than natural, but on cutting into it it has invariably exhibited a natural structure.

The kidneys are subject to various diseases, and very different morbid structures are exhibited in them in cases of dropsy. Dr. Bright thinks that his investigations will authorise three varieties generally attended by albuminous urine;—"In the first a state of degeneracy exists, which, from its appearance, might be regarded as marking little more than simple debility of the organ" (anæmia). "In this case the kidney loses its usual firmness, becomes of a yellow mottled appearance externally; and when a section is made, nearly the same yellow colour, tinged with grey, is seen to pervade the whole of the cortical part, and the tubular portions are of a lighter colour than natural. The size of the kidney is not materially altered, nor is there any obvious morbid deposit." This state of the kidney is well known as the consequence of dram-drinking, but it certainly is not confined to the victims of intemperance. It is frequently found in patients who have suffered from tedious and exhausting disease; and Dr. Bright himself states that he had observed it in a case of diarrhoea and phthisis, and of ovarian tumour. We have observed it in a woman who died from disease of the heart, and in whose lungs there were softened tubercles, none of which had been discharged. In this instance the urine did not afford the slightest coagulation by heat. In the most advanced stage of this disease Dr. Bright thinks that there is a more decided alteration of structure, and that some portions are consolidated so as to admit of very partial circulation; in which state the surface has a somewhat tuberculated appearance, the projections being paler than the rest, and at this period the urine is coagulable.

The second form is one in which the whole cortical part is converted into a granulated texture, and where there appears to be a copious morbid interstitial deposit of an opaque white substance. In its earliest stage this only produces externally an increase of the natural mottled appearance, or sometimes that of fine sand sprinkled more abundantly on some parts than others. The same appearance is slightly observable internally on making a longitudinal section. After the disease has continued some time, the deposited matter becomes more abundant, and innumerable specks of no definite form are observed on its surface. The cortical part exhibits, on being cut into, a similar appearance. Later in the disease, the granulated state begins to show itself externally in frequent slight uneven projections on its surface, and the kidney is rather larger than natural.

In the third form the kidney is quite rough and scabrous to the touch externally, and rises in numerous small projections, yellow, red, and purplish. The organ is often inclined to be lobulated, and on making an incision, the texture is found approaching to cartilaginous hardness. The tubular portions are observed to be drawn nearer to the surface, and it appears like a contraction of every

part of the organ, with less interstitial deposit than in the last variety.

Dr. Bright also mentions two other conditions of the kidneys, in which coagulation of the urine is sometimes observable. One of these consists in a preternatural softness of the organ; the other in the blocking up of the tubular structure by small portions of a white deposit, bearing the appearance of small concretions. In the former, a corresponding loss of firmness has been observable in the heart, liver, and spleen; and in the latter, the cortical portion has been firmer than usual, and the tubuli have assumed a waved direction.

These are by no means the only diseases of the kidney that give rise to or are attended by dropsy. It is sometimes scrofulous. We have seen it converted into a scatomatous tumour so large that it formed a prominent tumour in the abdomen. In another case the right kidney was five or six times its natural size, soft, and divided into lobules. On opening it, it was found full of scrofulous matter, which occupied the whole of the cortical part and the interstices of the tubuli, which were scarcely at all traceable. The left kidney equalled the right in size, but was less diseased. The cortical substance was changed into a granulated fatty substance, presenting much the appearance of the liver under some circumstances. The tubuli were in this instance quite distinct. In this case, which is copied from notes taken in 1826, the urine had come away stillatim, and the patient had suffered very much from excoriation of the pudenda. She never complained of any particular pain till six weeks before her death, when she became anasarcaous. The symptoms then agreed with those of Dr. Bright's and Dr. Gregory's cases. From the urine during the whole period coming away stillatim, this secretion was not particularly examined. We have particularly mentioned this case because it illustrates the remark of Dr. Gregory, that the persons in whom he found the morbid alterations of the kidney, were either those who had led irregular lives, or who presented the usual character of the strumous diathesis. Again, in a case which we examined a few days ago, the left kidney contained several calculi; and its structure, though much wasted, was remarkably healthy in appearance, while the right kidney was pale, and the tubuli were very indistinct in consequence of an interstitial deposit of a whitish substance.

These, probably, are only a few of the deviations from health which occur in the kidney, and which give rise to or accompany dropsy. With regard to any of these changes being necessarily connected with albuminous urine, enough has been shown above to prove that at present the subject requires additional investigation. We have found albuminous urine to a very considerable extent, without any corresponding alteration in the structure of the kidney; and we have related one instance of Dr. Bright's first variety, in which the urine did not coagulate. It cannot, however, be considered improbable that this phenomenon is connected with some peculiar condition of the organ, and that, when long continued, it will lead to some peculiar morbid alteration of structure. But what this condition or this alteration may be, must still be regarded sub judice; and we should

mislead our readers in no slight degree if we called upon them to believe that anything further in this matter has yet been discovered, than a more frequent coincidence between coagulable urine and disease of the kidney than had been previously suspected. This coincidence, though frequent, is not invariable; nor are the symptoms which are reported to indicate it more to be relied upon. [See KIDNEY, DISEASES OF THE].

**Prognosis.**—The prognosis in dropsy must naturally vary much according to its origin, its combination with organic disease, its duration, and the debility of the individuals who are the subjects of it.

Acute dropsies, *cæteris paribus*, are more curable than chronic, and idiopathic are more curable than secondary dropsies. With regard to acute dropsies our judgment must be greatly guided by the concomitant circumstances. If there be any vital organ seriously affected, as the lungs or the heart, our chance of removing the effusion will be governed greatly by the control we may be able to obtain over the original disease. Thus, if anasarca succeed bronchitis, a permanent recovery from the dropsy cannot be expected without the disappearance of the bronchitis. It will indeed sometimes happen, as we have mentioned in a previous part of this article, that effusion will disappear a short time before death; but this clearly is no cure of the secondary disease. In healthy constitutions, which have been uninjured by irregular habits of living, the acute dropsy will, under proper treatment, usually terminate favourably; but in those who have been weakened by drinking or other irregularities, or who are originally of debilitated constitutions, we can seldom venture to predict recovery.

With regard to secondary dropsy, we may state that those arising from disease of the heart usually admit of removal, but the disappearance of the effusion is seldom permanent. Nevertheless, longer or shorter intervals of ease are afforded; and, under cautious treatment, months, and even years may elapse between the first occurrence of effusion and the fatal termination. The same remark to a certain degree holds good of that species of dropsy which accompanies disease of the lungs, but it is certainly less curable than the former species. The effusion which succeeds hepatic disorders is almost always fatal, and by no means affords a chance of cure in an equal degree with the two former modifications. There are, however, some cases of ascites connected with enlargement of the liver, in which the effusion will disappear repeatedly under the use of diuretics, and in a few instances we have known a considerable time elapse before it has returned. That which succeeds or is accompanied with extensive disease of the kidney seems absolutely incurable when the renal disturbance has produced any extensive change of structure; but the symptoms of this change are by no means at present satisfactorily ascertained.

**Treatment.**—In the treatment of dropsy, as in every other disease which falls under the care of the physician, certain general principles are first to be considered; and, secondly, the circumstances by which these principles are more or less modified.

It has already been stated that dropsies are sthenic or asthenic, or in different periods of their

progress that they partake of both conditions—at one time the sthenic, at another the asthenic predominating. To this point, then, attention must first be paid, and an antiphlogistic or a contrary regimen pursued accordingly.

Should the effusion have arisen suddenly, and should local inflammation be present, whether of the lungs or any other organ, bleeding must by all means be resorted to; and it must be carried far enough to affect the system, to reduce the pulse, produce faintness, or relieve the immediate inflammatory symptoms.

The bleeding may be repeated should the inflammation continue, and should the strength of the patient permit. But even when this is much reduced, and venesection can scarcely be justified, local bleeding may be advantageously employed, and in all such cases cupping is much more efficacious than leeches. The glasses should be applied as near as may be possible to the affected organ, and to the part of the organ which is most implicated. Accordingly, in disorders of the lungs, the blood should be drawn from the region of the chest; and if, which will frequently occur, one part of the organ is particularly affected, the glasses should be applied opposite to it. The same remark holds equally good in dropsy connected with inflammation of the pleura. In this case the chest should always be examined without covering, for by its dilatation, contraction, &c., much additional assistance is afforded to the diagnosis. Next to bleeding, counter-irritants are indicated in all those cases in which there are local affections, and it may be necessary to continue these for a considerable time. Indeed, in all chronic disorders, if counter-irritation be advisable at all, it is advisable to persist in it, either till the disease for which it is employed has disappeared, or till the strength of the patient seems to suffer from its effects. Whoever has examined a dropsical patient when pleuritis has been present, must have remarked the presence of factitious membranes of very different ages, and in comparing them with the previous symptoms he will usually be able to fix upon precise periods at which some of them were first formed. A little further reflection will lead him to the conclusion that at no time had the tendency to pleuritic inflammation been completely overcome, and although, at particular stages, evident and very severe exacerbations had taken place, yet that through the whole disease the inflammatory action had more or less persisted. Under such circumstances, reason clearly points out one course, viz., to continue the remedy while the slightest trace of inflammation remains. In inflammation of the pleura, (perhaps of serous membranes generally,) this is particularly necessary, for it is not always painful, and may proceed a great way without exciting surprise. And it is this point that appears to us most important in that species of dropsy to which Dr. Bright has assigned the morbid state of the kidney for its origin. We have already expressed our doubts whether in the majority of such cases the inflammation of the serous membrane be not the primary disease; at any rate it is frequently concomitant, and in no slight degree accelerates a fatal termination. Under such circumstances it is to the local inflammation and not the effusion that attention must be paid;

if the former continue, the disappearance of the latter will be of no avail. Bleeding is not only called for in dropsy when local inflammatory symptoms are present; a general state of plethora equally demands it. Our chief dependence for an accurate diagnosis in this case is the full hard pulse, and in great measure also the history of the patient. We cannot, however, too strongly inculcate the necessity of care in bleeding individuals of irregular habits, and who have indulged excessively in drinking, especially spirit-drinking, or in any other debilitating vice. Whatever may be their appearance, or however hard and firm their pulse, such persons ill bear extensive sanguineous depletion; they sink rapidly afterwards into a low typhoid state, without the possibility of rousing the system to healthy and energetic action.

Of the two principal modes of overcoming inflammation, bleeding and counter-irritation, we have perhaps for this place said enough. Of internal remedies, the two most powerful unquestionably are the antimonium tartarizatum, and calomel in combination with opium. The former, to be really serviceable, should be administered in the doses recommended by the Italian physicians, and thus given, its efficacy in inflammation is most extraordinary. Nor is its effect merely felt in depressing the inflammatory action; it acts upon the bowels and upon the skin, and thus, not unfrequently, by promoting the functions of these organs, but especially of the last, it favours even directly the removal of the effusion. The principal inconvenience which is experienced from this medicine is the nausea and sickness which it induces, particularly after the first few doses. This, however, in most cases soon disappears, and the patient is able to take from one to three or even four grains at a dose without the slightest nausea. It will indeed occasionally happen that an individual cannot obtain what has been well termed the *tolerance* of the medicine; this, however, is so rare a case that it does not contradict the general position. Calomel and opium have been long known as peculiarly useful in those inflammations which throw out plastic lymph, such as iritis, cynanche laryngea, &c. These, however, are by no means the only forms of inflammation in which calomel and opium may be advantageously substituted for venesection or any other mode of bloodletting. Whenever the strength of the patient is too much reduced to admit of farther sanguineous depletion, while still the inflammatory symptoms continue unsubdued, this combination may be usefully employed. It should be given as frequently as every three hours, and according to the age of the patient the dose may be proportioned from two to four grains of calomel, with from half a grain to two grains of opium, every time. It may be continued till the mouth becomes slightly affected, but it will be seldom advisable to carry it farther than this. What has been now said merely refers to the subduing of any inflammation which may be present, which may give rise to or accompany the dropsical effusion. But to these we may often add diuretics or purgatives. Of the different articles which are employed for this purpose we shall speak more particularly in a subsequent part of this article. We here only inu

mate that in addition to the plan for overcoming any local inflammation or general plethora, we are also called upon to attempt the removal of the effusion by stimulating the secretions of the bowels and kidneys.

While on the one hand we frequently find dropsical effusion united with inflammation, so on the other the system is sometimes, though perhaps more rarely, in a state of general debility. In this last condition a very opposite practice must be adopted, and the most powerful tonics, such as quinine and the different preparations of steel, may be not only safely administered, but may even be demanded. We must not, however, forget that mere weakness will not justify the use of these remedies, because this may and frequently does occur when local inflammation is present. A greater object will therefore be to distinguish these different states; for what will be useful to the one will unquestionably be injurious to the other. For the diagnosis we must refer to the histories of dropsies as we have laid them down in the present article, and under *ASCITES* and *ANASARCA*. When, after proper investigation, we are fully satisfied that the system is in a state of great general debility, the sulphate of quinine and the different preparations of steel may be given. It will, however, often happen that a debilitated patient cannot bear such powerful tonics, and that their stimulating power produces feverishness and general irritation. In this case we may have recourse to the vegetable bitters, and if the patient is very feeble, the Iceland moss will be found to be one of the most useful remedies which the *Materia Medica* affords.

Between these two plans, however, we may be called upon to take a middle course, and alternately to depress and support the strength of the system, accordingly as inflammatory symptoms or the reverse predominate. Here reliance must be placed upon the judgment of the medical attendant. Under such circumstances local depletion will generally be much preferable to general, and the peculiar symptoms will generally point to the affected organ. We have already stated that cupping, when it can be effected, is to be preferred to leeches, as the quantity of blood taken is more easily ascertained, and far less fatigue induced to the patient.

The remarks now made equally apply to every form of effusion, but some modification of treatment is peculiarly called for according to the organs from which the dropsy derives its origin. It is to these points, therefore, that we now more particularly call the attention of our readers.

*Treatment of Dropsy connected with Disease of the Heart.*—Next to the general considerations which have already been mentioned, we have to recollect that any obstruction in the flow of blood from the right to the left side of the heart will be very likely to produce congestion in the lungs, and for the relief of this symptom we may be called upon merely to diminish the general mass of blood in the system. And again, should the size of the heart be greatly increased, even though no very material disease should exist in the valvular structure of the organ, the lungs may be so compressed that they may be unable to receive, without inconvenience, even their usual complement

of blood; and for this cause also depletion may be necessary. These observations may not appear to bear immediately upon the treatment of dropsical effusions, but without a reference to the organs upon which such effusions depend, it will be impossible in any case to conduct them to a successful termination. Our first attention then is due to the condition of the heart and its influence upon the lungs; our second must be directed to the dropsy itself.

In the first place, we must consider whether there exists a sthenic or asthenic state of the general system. If the former prevails, recourse may be had to drastic purgatives, particularly to elaterium and croton-oil, with or without previous bloodletting, according to circumstances; and in few cases does more good effect follow the exhibition of remedies. They must be repeated every two or three days till the effusion entirely disappears. By this means we must not, however, expect that the dropsy will be prevented from returning; but considerable intervals of ease will be afforded, and the patient may be enabled to live comfortably for several years, the dropsy occasionally recurring and being restrained by treatment.

Some patients, however, ill bear excessive purging, and we are then compelled to use other means, and chiefly diuretics. Of these the digitalis *purpurea*, or common fox-glove, is one of the most efficacious in the effusion which depends upon disease of the heart, and which is connected with some degree of debility. In this respect our experience corroborates the opinions of Drs. Withering and Blackall, that it is most successful where the debility is completely marked, the countenance pale, the pulse weak, and the muscular energy lessened. We have usually preferred the infusion, and have administered it in half-ounce doses two or three times a day, till it has increased the urine, had a decided effect upon the pulse, or produced some other of its peculiar consequences.

The propriety of giving digitalis in cases of debility naturally suggests its use in those cases in which it is necessary to commence the treatment by bleeding; and accordingly this plan was recommended by Dr. Withering, and has been confirmed by Dr. Blackall, as probably by most physicians who have paid much attention to the action of this drug. Dr. Blackall has mentioned one symptom which is decidedly opposed to the exhibition of digitalis, viz. "a membranous tense pain in the head, sometimes over one eye, with a sort of disturbance of the brain, which occasionally attends an overdose before any bad signs have appeared; if neglected, it is followed by convulsions." The same physician also remarks, very correctly, that when the urine is decidedly increased, the digitalis ought to be suspended, as its debilitating effects are then apt to become greater than the system can bear with impunity. The diuretic effect of digitalis is sometimes greatly increased by its combination with opium, as indeed is the case with many other diuretics.

Sometimes the dropsy consequent to disease of the heart occurs in such a state of general debility, that somewhat of a tonic plan is required. We have repeatedly seen such a state occur in

females, in whom there has been either a miserable hysterical state, or positive and decided hypochondriacism. Active stimulants, it is evident, must be as injurious to such patients as depleting measures; both, though from different causes, will increase the turbulent action of the heart and the distress of the patient. Under these circumstances we have found great benefit from the ferum tartarizatum, either in combination with a tonic or with a diuretic, such as the infusum genisteæ or the infusum taraxaci; these appear to strengthen the system generally, while they act powerfully upon the kidneys.

In the latter, or rather the last stage of this species of dropsy, the anxiety, or we might say the anguish of the patient, is inconceivably painful to witness. Often the mind remains unclouded, and all the natural feelings of affection for relatives, and attachment to life for their sake, remain unimpaired. When the disease has attained this point, it is only in our power to afford temporary and very imperfect relief by means of opium and ether. These must be given in frequent doses, and large enough to ensure their specific effect. Fortunately, painful as is the stage we are now considering, it does not last long; the patient shortly falls into a state of stupor, and sleeps, as it were, to death, or dies instantaneously, and very unexpectedly to the attendants.

*Treatment of Dropsy connected with Disease of the Lungs.*—On this form of dropsy we have not much to add to the remarks which we have just made with regard to the effusion when connected with disease of the heart. Bleeding, general and local, may be and frequently is necessary; and, in addition to this, counter-irritation, especially by means of the tartrate of antimony, ought strictly to be enforced. With respect to medicine more immediately calculated to remove the effusion in this as in the preceding form of dropsy, we are chiefly dependent upon purgatives and diuretics. With regard to the former, they ought never to be exhibited while we suspect the lungs to be the subject of inflammation. It is, we believe, a remark of Sydenham, that violent purgatives are injurious in pneumonia, and we have had frequent occasion to confirm the opinion. When, however, effusion is present in the chest or in the lungs, without any sensible inflammatory state, the drastic purgatives frequently afford the most remarkable relief, and sometimes suffice alone for the entire removal of the dropsy. As a diuretic, digitalis appears less serviceable in dropsy consequent to disease of the lungs, than where the heart is the original seat of disorder. Squills, however, in combination with laudanum and the neutral salts, particularly the sulphate of magnesia, act very powerfully upon the kidneys, and in some instances speedily and entirely remove the effusion. It is in this form of dropsy that the super-tartrate of potash deserves the greatest confidence, as it keeps up a constant flow from the kidneys and the bowels together, without inducing that debility which drastic purgatives or digitalis are so apt to occasion.

*Treatment of Dropsy connected with Disease of the Liver.*—This is probably the most difficult of any species of dropsy to treat successfully, in

consequence partly of the broken-down constitution in which it generally occurs, and partly from the obscurity in which the different diseases to which the liver is liable are involved. When we can satisfy ourselves that this organ is the subject of inflammation, without any remarkable change in its structure, local bleeding and counter-irritation are required in the first instance; and, in the second place, those internal medicines which are known more particularly to act upon the biliary secretions, such as the different preparations of mercury, and the nitro-muriatic acid. Mercurial frictions may also be had recourse to with advantage in very many cases. The mercury should be persisted in till the mouth is affected, and benefit has sometimes been derived from keeping up salivation for a considerable time. In addition to placing the system under the influence of mercury, some medicines are required more immediately to act upon the kidneys, and through their increased action to carry off the effused fluids. In the article ASCITES we have mentioned the utility of combining many diuretics together; and in the form of dropsy that we are now considering this practice is more particularly demanded. Among the most efficacious under these circumstances are squill, colchicum, liquor ammoniæ acetatis, and the spiritus ætheris nitrici, given in combination of two or more, and administered every three or four hours. When, however, the colchicum is given, much attention is necessary that it does not induce its peculiar symptoms, which are precisely those of cholera. This may take place in peculiar constitutions after a single dose only, but more commonly, like digitalis, it accumulates in the system, and its effects are not developed till after the medicine has been continued for several days. Digitalis is not often applicable to dropsy connected with extensive hepatic disease, as its debilitating effects are greater than patients so affected can bear. Dr. Fowler made very numerous and satisfactory experiments upon the nicotiana tabacum, and why this medicine should so completely have fallen into desuetude it is difficult to determine. It is certainly one of the most powerful diuretics which the Materia Medica contains, and we have never seen any evil effects resulting from its use. It has appeared to us particularly useful in dropsy connected with enlargement of the liver and spleen, but little to be relied upon when the principal disease is situated in the chest. The reports of Dr. Fowler are unfortunately not full enough to enable us to draw any very accurate conclusions as to the nature of the diseases in which he found it most beneficial; but five of the successful cases in which he used it were the consequence of agues; and enlargement of the spleen is well known to be a common consequence of this disorder. The form we have used is the infusum nicotianæ of Dr. Fowler, which is made by pouring a pint of boiling water upon an ounce of tobacco. This is suffered to macerate for an hour in a covered vessel, and fourteen ounces only are strained off, to which two ounces of rectified spirits of wine are added to make it keep. Thirty drops are given at first three times a day in water, and the dose is gradually increased, till it augments the flow of urine, or produces sickness and giddiness. The dose has been carried,

by Dr. Fowler, as high as one hundred and eighty drops at night, and one hundred in the morning.

With the exception of abstaining from mercury, it does not seem necessary to lay down any other plan than what has now been referred to, when the disease of the liver amounts to change of structure. It ought, however, to be always kept in mind, that when the liver is tuberculous, or we have reason to believe that it is affected with hydatids, mercury may weaken the patient, but can have no effect upon the disease. How far under such circumstances it may be advisable to try iodine, or the muriate of lime, may be very properly a subject of consideration. In a case of apparent simple enlargement of the liver, in a girl of twelve years of age, but unconnected with dropsy, we certainly derived great advantage from employing the former, and under similar circumstances, connected with effusion, we should certainly be inclined to afford it a trial.

*Treatment of Dropsy connected with Disease of the Kidney.*—Dr. Bright, who has most attended to this subject, appears to lay the principal stress upon the supertartrate of potash; but in this, as in every other modification of dropsy, reference must first be had to general principles. We have already stated our opinions at some length respecting the signs by which the affections of these organs may be ascertained. When, therefore, we feel convinced that the kidneys are diseased, the same rules which have been laid down for the treatment of other local disorders will apply here, and local depletion with counter-irritation must be as proper in the one case as in the other. At the same time we confess that on this point we have not experience for our guide, so far as this particular organ is concerned. We may, however, mention a fact that has been related to us on good authority connected with diabetes mellitus, and which has some analogy with the disease now under consideration. The medical man to whom a patient with this disease applied, and from whose urine he had collected a considerable quantity of sugar by evaporation, rubbed in the unguentum antimonium tartarizatum over the loins; and while the irritation was kept up, the sugar entirely disappeared from the urine. Other symptoms, however, supervened, which compelled him to suspend the ointment, and the sugar was again found in this fluid. The supertartrate of potash has the same effect in this dropsy as when disease of the lungs or pleura is present. We are sorry to say that we have little more to add on this subject, as it is one to which at present little attention has been paid, and respecting which our actual knowledge is any thing but precise. We would, therefore, most strongly inculcate the observance of general principles in its treatment, till farther investigations shall have clearly demonstrated those peculiar modifications of practice which may be demanded by the particular organ.

[Observers have differed in regard to the propriety of administering diuretics in the dropsy occasioned by the disease of the kidney, described by Dr. Bright. By most, they have been considered unadvisable, especially in the early periods; but they are advised by M. Rayer, who prefers *cochlearia armoracia*. Notwithstanding the argu-

ment of Dr. Christison (*On Granular Degeneration of the Kidneys*, Edinb. 1839, and Philad. 1829, and art. Granular Diseases of the Kidney, in Tweedie's *Library of Practical Medicine*, Amer. edit. iii. 271: Philad. 1842) that an agent which increases the secretion of an organ may not add to existing disease in that organ, diuretics must be considered equivocal remedies; and, upon the whole, Dr. Christison is desirous of so regarding them in the disease under consideration; but he is of opinion, that the "dread of an evil influence from them over the primary disease has led several estimable authorities to forbid their employment likewise in all secondary affections, in some of which no other remedies are so promptly efficacious."]

We may here very properly terminate our consideration of particular forms of dropsy. They, however, by no means exhaust the subject; and careful observation would probably find signs no less marked in effusion occurring after the disease of other organs, and a consequent propriety of modifying the treatment. What we have already said will, we trust, afford a somewhat clearer view of the principles upon which dropsy ought to be treated, than has yet been published. It will show that certain general principles apply to all, but that these are more or less modified according to particular circumstances, and the organs which give rise to effusion in the first instance, or become involved in the course of the disease. There is nothing empirical or irrational in this treatment. Dropsy is not (as it is too often regarded by men even highly intelligent and much engaged in practice) the consequence either of debility alone or inflammation alone; it is neither always a sthenic nor asthenic state of the system in which it occurs; it may be one or the other, or the one may alternate with the other. Since we find that different organs are the original causes of effusion, the treatment of the local diseases is not to be neglected in the great anxiety to remove the dropsy. Neither is effusion to be neglected; but we are to use different remedies according to the organs which are affected. Some of these we have endeavoured to point out; in doing so we do not pretend to be free from error; but the road is opened for others, to pursue a similar line of observation. If this is carefully followed, we do not question but that a few years will add a mass of information respecting the peculiar power of medicines in this disease, which may go far to diminish its present ill repute, as one of the opprobria medicinæ.

*Of the particular remedies employed in Dropsy.*—We should not consider that we completed the subject of the treatment of dropsy, did we not offer a more complete record than we have yet done of the various medicines which have been proposed as specifics in this disease. We may comprehend these under the various heads of purgatives, diuretics, emetics, sudorifics, tonics, frictions, scarification, acupuncture, paracentesis. The operation of some of these we have already discussed, and here, therefore, we shall do no more than enumerate them.

*Purgatives.*—The principal of these are the *croton tiglium*, from which the croton oil is expressed, and in which form alone we know the remedy in this country. The dose is a single

drop, and this will operate in many instances most violently, producing within half an hour sickness, vomiting, and profuse alvine discharges. Dr. Good recommends the alcoholic solution first proposed by Dr. Nimmo, but we have never found the oil do any real mischief. There are individuals upon whom it will not act at all, or who require four or five drops to ensure the operation. With such idiosyncrasies the oil must of course be given in the larger dose.

Elatarium is also given with the same intent. We have mentioned under the article ANASARCA, the form we prefer, viz. two grains of elatarium (or half a grain of *elatin*) combined with a scruple of the extract of gentian, and divided into four pills, one to be given every hour till free evacuations are procured.

The common elder and the dwarf elder (*sambucus nigra*, *sambucus ebulus*) have formerly enjoyed a high reputation as hydragogues; and the former is particularly recommended by Sydenham. Every part of these plants is emetic and purgative, but the most potent is the inner bark, which may be taken in powder or infusion. The dose of the former is said by Dr. A. T. Thomson to vary from five grains to half a drachm; we have, however, no personal experience upon the subject, nor can we say to which species of dropsy it is most applicable. If the remark of Sydenham be correct, that it acts equally upon the kidneys and bowels, we should expect it to be particularly serviceable in effusion connected with disease of the liver, when it is thought advisable to unload the system quickly, as experience seems to prove that ascites (and this is the form which usually accompanies hepatic disorder) usually yields more completely to diuretics than to purgatives.

*Rhamnus catharticus*, or common buckthorn, is another hydragogue highly praised by Sydenham, but which, like the elder bark, has gone out of fashion. Sydenham employed it in syrup, and states that it removes the effusion without disturbing the circulation, or rendering the urine higher coloured, as other purgatives are accustomed to do; but that it has the inconvenience of inducing excessive thirst. The dose of the recent berries is one scruple, that of the dried berries a drachm. The dose of the syrup prepared according to the London Pharmacopœia is from half an ounce to an ounce, the patient drinking freely at the same time of demulcent fluids.

*Helleborus niger*, or black hellebore, has also been used as a hydragogue; and Avicenna,—no mean authority so far as the mere action of remedies is concerned,—observes that he had seen more wonderful effects from it than from any other remedy—"but it will not always equally work wonders." The dose as a hydragogue is from ten grains to a scruple. In the employment of black hellebore much care is necessary that the extract be fresh, for, by keeping, it appears very soon to lose its medicinal qualities. The dose above-mentioned may be repeated at the end of six or eight hours if no operation shall have ensued; but in practice the utmost caution is necessary that the peculiar poisonous effects do not follow. In some individuals the smallest dose induces inconceivable anxiety. In the few instances where this has occurred in our own experience, the individuals

were known to be incapable of bearing the mildest narcotic medicines, from the intolerable distress which always followed their exhibition.

Many other purgatives, as gamboge, jalap, scammony, neutral salts, have at various times been in vogue for the cure of dropsy, but it scarcely seems necessary to speak of them here more particularly. They all in great measure act in a similar manner, viz. by producing free watery discharges, and thus stimulating the absorbent function. The super-tartrate of potash is rather a mild aperient than a purgative, and occasionally acts also most powerfully as a diuretic. It is remarked, however, by Dr. Ferriar, that it sometimes "neither increases urine nor stool, yet it cures." Its use in dropsy was, we believe, first particularly pointed out in this country by Dr. Home, and in his reports he has related twenty cases in which it was employed. We collect generally from them that it was most beneficial where there was an inflammatory action present in the system, and where there was no actual organic disease. At the same time it appears in some instances to have been serviceable where the liver was deranged. Its action is chiefly that of an aperient, producing profuse watery evacuations, without exciting thirst or feverishness. Dr. Thomson states the dose as a hydragogue to be from four drachms to six drachms, in an electroly. Dr. Mason Good says that in order to ensure its aperient action, it ought never to be given in less than ounce doses; but our experience by no means corresponds with this. We have frequently succeeded by giving only drachm doses three or four times a day: after the second day profuse watery evacuations often follow to such an extent that we are obliged to suspend the medicine. In the intervals the milder tonics may be advantageously employed. (See CATHARTICS).

*Diuretics*.—Digitalis holds the first place, in modern times, in this class of medicines; but as, in the course of this article, we have already mentioned the circumstances which render it most appropriate in dropsy, we shall only refer the reader for a more particular account of this drug to the article DIURETICS.

The squill is certainly a very powerful diuretic, but its powers are much increased by uniting it with other diuretics, particularly the neutral salts. In some cases, where the inflammatory action is at all high, its operation is greatly favoured by small doses of blue pill administered in such a manner as slightly to affect the mouth. Dr. Blackall observes, that it is much to be depended upon, when, with an oppression of the chest, the urine is scanty, high-coloured, and without serum. How far this last remark is perfectly correct may be questioned; but that it is highly serviceable when the urine is high coloured, is perfectly in accordance with our own experience.

The attention of British practitioners was first called to the diuretic properties of the *pyrola umbellata* by Dr. W. Somerville, and they are so well attested, that we cannot but regret that more attention has not been paid to it. It is a native of North America, and belongs to the natural family of Ericacæ. The latest account is that of Dr. Bigelow, professor of Materia Medica and Botany in Harvard University, in the United States. "In a number of dropsical cases," says

this gentleman, as quoted by Messrs. Churchill and Stephenson, "when first given, it made a distinct and evident impression on the disease, communicating an increased activity to the absorbents, followed by a great augmentation of the excretion from the kidneys. The benefit, however, with me, has been in most instances temporary, and it was found better to omit the medicine for a time, and to resume it afresh, than to continue it until the system had become insensible to its stimulus. After suspending it for a week or two, the same distinct operation took place on returning to its use, as had been manifested in the first instance. It proved in almost every instance an acceptable medicine to the patient, and was preferred, both for its sensible qualities and its effects on the stomach, to other diuretics and alteratives which had been prescribed." The paper of Dr. Somerville, which is contained in the fifth volume of the *Medico-Chirurgical Transactions*, is valuable from the post-mortem examination of Sir James Craig, to whom the plant had afforded very important benefit. In this instance the liver was studded with innumerable tubercles, the peritoneum throughout was thickened, and the intestines were glued together with coagulable lymph.\* The lungs on the left side were sound, but compressed on the right side by three pints of water. The pericardium contained six ounces of water, and the heart was somewhat larger than usual. The history of this case abundantly proves that the original malady was in the liver. According to Dr. Somerville, the virtues of this plant do not reside in any volatile principle, and he found consequently that a decoction acted much more energetically than an infusion. In order to make this decoction, an ounce of the dried plant, including the root, stalks, and leaves, is cut into small pieces, and macerated twelve hours in two pints of cold water, and then boiled till it yields one pint of strained liquor. Mr. Carter found that thirty-four pounds avoirdupois of the recent herb produced four pounds of extract, which had the same properties with the decoction. Five scruples of this extract in pills or in solution may be given in twenty-four hours.

The *spartium scoparium* or common broom, the *leontodon taraxacum* or dandelion, the *apium petroselinum* or common parsley, the *juniperus communis*, and the *colchicum autumnale*, all possess considerable diuretic powers, and may frequently be united with some of those above mentioned, with much advantage. The meadow-saffron is perhaps the most powerful of all these, and we have succeeded with it in conjunction with mercurials, in acting upon the kidneys in hepatic disease when no other remedy had any effect. The *spiritus colchici ammoniatus* of the London Pharmacopœia is the preparation which we have chiefly relied upon, given in half-drachm doses three times a day, with a blue pill night and morning, and sometimes mercurial frictions over the abdomen being added.

In the 57th number of the *Journal Hebdomadaire*, for October, 1831, M. Lemasson has given a detailed account of the employment of the bark

of the root of the *chiococca racemosa auguifuga*, or snow-berry tree, belonging to the natural family of the *Rubiaceæ*. This bark furnishes a bitter principle, crystallizable in delicate needles, without smell, of a bitter and rather an astringent taste, soluble in water, very soluble in alcohol, especially when warm, and reddening the tincture of turnsole; in this principle all the peculiar medical properties reside. This remedy is said by M. Lemasson to be chiefly applicable to atonic dropsies. A decoction of the bark is made by macerating two drachms of the bark in eight ounces of water, then boiling for ten minutes, and straining the liquor off, which is divided into two doses, and the second dose is taken two hours after the first. The cases related by M. Lemasson are all connected with great general debility of the system. One was a case of chronic bronchitis with slight dilatation of the heart, and in this patient the feebleness was very considerable. Two were the consequence of syphilis and mercurial courses, to which universal anasarca succeeded, but without any particular visceral disease. In one patient affected with dilatation of the right cavities of the heart, the exhibition of the bark was preceded by bleeding. The effect in all was an improvement of the appetite, and a great increase in the flow of urine. The medicine is administered as above-mentioned in two four-ounce doses, with an interval of two hours between the first and second dose; when this affects the kidneys, they continue their action for several days, and the medicine is not again exhibited till the urine diminishes. In the first case which was related, it was given on the 18th of June, on the 20th of the same month, and not again till the 5th of July, after which it was not repeated. In the second case it was only given twice. On the 22d of May, and on the 29th, both terminated successfully, and the medicine had a similar effect of increasing the appetite and the flow of urine together.

*Emetics.*—These have been recommended by some authors, and cases have been given, in which they have succeeded when other remedies had failed. We have ourselves no experience of their effect in this disease, and they appear to be banished from modern practice. We shall content ourselves therefore with this intimation.

*Sudorifics.*—These are unquestionably in some cases highly useful, more particularly however when disease of the lungs is present. The vapour-bath has occasionally been successful in such cases. The celebrated Dampier cured himself by covering himself all over with sand, heated by the sun, in California, for an hour, after which "he was carried to his bed and well covered with clothes, where he fell into a profuse sweat, after which he recovered daily." The compound ipecacuanha powder has in this way been successful, and we have seen ascites attended with liver disease removed by it, though the patient died soon after, from the original malady.

*Tonics.*—Every species of dropsy may in some part of its course require the exhibition of tonics, for a state of debility easily follows depletion, however necessary it may have been; and it has not unfrequently happened that a patient has been cured of dropsy, and died of the weakness induced by the remedies. To obviate this, appears to

\* As, however, he had been frequently tapped, this last appearance was probably a consequence of the operation and not a part of the original disease.

have been the object of the celebrated electuary of Dover, which is a combination of scammony, sulphuret of iron, and crude mercury. Of this formula Dr. Blackall says, that "it has certainly performed many cures, and there is so much debility in the disease, that the addition of tonics to purgatives, never indifferent, is particularly desirable here, where it can be made with safety." Steel and bark are the principal tonic remedies that have been used in dropsy, and we consider the ferrum tartarizatum to be the best preparation of the former, as it unites a diuretic with its tonic properties. We have usually given it in combination with infusum calumbæ, and particularly in those asthenic dropsies in which the heart or lungs are diseased. In the asthenic dropsy consequent to chronic bronchitis, united with counter-irritation of the chest, it will sometimes alone remove the effusion. The sulphate of quinine is given with the same intention, and in weak and scrofulous habits it seems preferable to the preparations of steel. Dr. Blackall prefers bark also in the debility consequent to dropsy after an acute disease. In the exhibition of these tonics the utmost care is necessary that they are not given in an inflammatory state of the system, nor while the tendency to inflammation remains; but when by bleeding, digitalis, and other evacuants, the effusion has nearly disappeared, and the urine recovered its natural state and quantity, tonics will complete the cure, and secure the patient from a relapse.

The action of the remedies just mentioned is more distinctly known than that of the tonic pills of Bacher, and which we have noticed under the article ASCITES. More like cream of tartar than common tonics, these pills seem sometimes to be merely anti-hydrotic, removing the effusion without inducing any increase in the urine or alvine evacuations. The dropsies in which we have found them most useful are those which occur in girls about the age of puberty, without manifest derangement of any particular organ, and we have observed them to be more useful in ascites than anasarca. The younger Bacher, in speaking of black hellebore, says that it is not applicable to cases in which the solids are firm, nor when the fibre is greatly relaxed and weakened, but when, with some degree of debility, the circulation is irregular, and determined to some particular organ. We may observe, however, that in many of the cases he has related, no such determination is indicated by the symptoms enumerated, and in our own practice they have seldom been of use, when there has been evidence of organic disease. The action of these pills, as we have already mentioned, is often imperceptible, but at other times they procure copious evacuations from the kidneys and bowels, and sometimes, according to Bacher, they cause profuse perspiration. The following is the formula of Bacher, as published by his son:—

R Extracti hellebori nigri,

Myrrhæ solutæ, aa, ʒi.

Cardui benedict. pulv. ʒiijʒi. M. s. a.

Fiat massa acra siccò exsiccanda, donec formandis pilulis apta sit. Singulæ ad grana sex.

Ten of these pills were given three times a day.

We have repeatedly cautioned medical practi-

tioners against the danger which may ensue from the poisonous properties of the black hellebore, and here therefore we shall only inculcate extreme watchfulness whenever this remedy is exhibited.

It is probable that many other of the common mineral and vegetable tonics may be employed in asthenic dropsy, and it will always be advisable that the practitioner should, as far as possible, be provided with substitutes, as, from particular idiosyncrasies, individuals are sometimes incapable of taking what may in other respects be the most appropriate remedy.

[*Methodical compression*, where it can be employed, is often of decided service in promoting absorption; at other times, it is employed only as a support when the integuments are largely distended with the fluid of dropsy. Frequently, the benefits from compression are more apparent than real—the fluid being simply forced from the cellular membrane pressed upon by the bandage, and returning to its former position when the pressure is withdrawn.]

*Friction*.—Under the head of ASCITES, we have referred to a case in the 49th volume of the Philosophical Transactions, in which friction with oil effected a cure in an old case of ascites. We are unacquainted with the particular symptoms which more particularly indicate this remedy, but there certainly can be no objection to it in any case in which the abdomen is free from tenderness.

*Blisters*.—These sometimes afford great relief, and we have often had recourse to them in our own practice. They are not, however, always unattended with danger, and whenever they are applied, the surgeon ought to be requested to attend to their progress. We have more than once seen death hastened by the blistered surface becoming inflamed, and mortification ensuing.

*Scarifications*.—These are indeed the opprobria medicinæ. They afford relief from the pressure and weight of the effused fluid, but too often at the same time give rise to inflammation, gangrene, and death. Yet there may be cases in which the distension is so great and the distress so intense, that the operation may not only be justified, but may be demanded. Upon this head we would briefly remark, that in old and very debilitated persons they should seldom, perhaps we might more properly say, they should never be practised, and that in young persons in whom the reparative process is more readily set up, great attention should be paid to their appearance and progress. The mere presence of dropsy will make no difference as to the proper manner of treating the wounds; but if inflammation be present, or gangrene, the same local and general remedies must be resorted to, as if no effusion had existed; nor indeed is this only useful to the wounds; frequently when the fluid has escaped, the tonic and stimulating remedies which the surgical treatment has required, have prevented the return of the effusion.

*Acupuncture*.—This is only a milder manner than scarification, of effecting the mechanical escape of the fluid; and the remarks made upon the former are equally applicable to the present remedy. Evil consequences are perhaps less fre-

quent, but still they do not unfrequently occur. (See ACUPUNCTURE.)

*Paracentesis.*—Of this operation we have spoken under the head of ASCITES, nor does it appear to us necessary to add to the remarks which we have there made.

*Diet.*—The only point that remains to be noticed is that of diet, but upon this head, we do not feel called upon to make many remarks, nor should we indeed have mentioned it at all, had it not been for the vulgar opinion which formerly prevailed, that fluids ought not to be allowed to dropsical patients. Even this notice is perhaps quite unnecessary, as the error is, so far as we know, completely exploded. Sir Francis Milman first examined the question, and gave the most satisfactory evidence that the restriction from fluids was not only not beneficial, but was in many cases even injurious; and since his time, so much additional evidence has been obtained to the same purpose, that to allow dropsical patients as much fluid as they wish to drink, is becoming an axiom in the treatment of disease. It has been well ascertained that many diuretics only stimulate the kidneys in proportion to the quantity of liquid in which they are given.

With respect to the nicer question of food, it seems unnecessary to make any remark: this must be varied with the nature of the dropsy, and the symptoms by which it is attended; and whoever understands the meaning of a phlogistic and antiphlogistic regimen will know how to apply either of these, or to vary from one to the other, in the disease of which we have been treating, as circumstances may require.

JOHN DARWALL.

**DYSENTERY.**—This word is derived from the Greek word *δυσεντερία*, which is compounded of *δύς* (*difficile, ægre, male*,) and *έντερον* (*intestinum*), and signifies that the intestines are morbidly affected. By Celsus the disease is named *tormina*, from one of its leading symptoms; and by Cælius Aurelianus *rheumatismus intestinorum cum ulcere*. Dr. Ballingall applies to it the not inappropriate appellation of *colonitis*. By certain French writers it is called *colitis* (colite), and in common language it is named *flux* or *bloody flux*, according as the intestinal discharges are free from blood or sanguinolent. It is placed as a genus in the class *pyrexia*, and order *profluvia* of Dr. Cullen; in the class *fluxus*, and order *alvifluxus*, of Sauvages; and, very correctly, in the class *hæmatica*, and order *phlogotica*, of Dr. Mason Good.

**Division of the Disease.**—Dysentery consists, in its early and acute stage, of inflammation of the mucous membrane of the intestines, especially of the colon and rectum. This inflammation, by implicating the other coats of the bowel, and by generating ulcers, may produce extensive and very intractable disorganization, giving rise to symptoms less acute than those of the early stage, but bearing a considerable resemblance to them. Hence it appears that there is a natural division of the disease into an acute and chronic form; the first consisting of inflammation, the second of its occasional effects, supervening on attacks of the acute disease, which have been imperfectly treated, or which our art has proved too feeble to subdue.

Various writers have proposed divisions of the acute stage into species, and complex arrangements of this kind are to be found in systematic works. From what has been stated respecting the nature of the disease, it will be manifest that any distinction between cases of uncomplicated dysentery must be principally founded either on the degree of inflammation, or the extent of intestine affected by it. The former circumstance unquestionably gives rise to various shades of discrepancy between different cases, but admits of no precise line of demarcation by which any assemblage of cases can be contradistinguished from others. The extent of bowel implicated in the disease constitutes a somewhat more important ground of distinction, for it is supposed that in the warmer regions a larger portion of intestine is affected with inflammation than in temperate climates; and that this circumstance, coupled with certain effects produced on the constitution by a high temperature, invests the disorder named by recent writers *tropical dysentery*, and by Sauvages, *dysenteria æquinoctialis*, with a peculiarity of character meriting special notice. It will hence appear that uncomplicated dysentery may be considered under two heads, the first comprising that form of the disease most frequently observed in temperate climates, whilst tropical dysentery is discussed under the second. It should be remarked, however, that though the distinction between the extremes of these varieties may be very manifest, intermediate degrees will be found, and such it has not unfrequently occurred to the writer of this article to observe in the south of Europe, which might be referred with almost equal propriety to either the one form or the other. Besides these varieties in the character of simple dysentery, its complications with other diseases require attention.

The following definition of dysentery will perhaps be found sufficiently precise:—Frequent mucous or muco-sanguinolent stools, pain in the abdomen, griping, and tenesmus, generally accompanied with pyrexia.

*The uncomplicated dysentery of temperate climates.*—Premising that many degrees of intensity are found in this affection, from the slight sporadic case in which the general health is but little deranged and no danger threatens life, to the wide-sweeping epidemic which has proved the scourge of fleets and armies, we shall present a sketch of as mild a form as the disease is almost ever observed to wear. A case of this description may commence with feculent and liquid stools, and they may become subsequently mucous, with occasionally a slight admixture of blood; or, they may be of the latter character from the beginning. There is little if any fixed pain in the abdomen; but considerable griping previously to the patient's rising to the night-chair, with a peculiar sense of working or commotion in the bowels, often referred to the situation of the sigmoid flexure of the colon; there is generally some heat at the anus, but the sensation extending thence up the rectum is one rather of irksomeness than of heat, and it induces very distressing straining, constituting the affection called *tenesmus*; the dejections do not exceed seven or eight in the day, and after they have acquired the mucous or sanguinolent character, traces of feculent matter are occasionally perceptible.

ble in them. Dysury is rarely observed, dyspnœa never, though both of these morbid states are very general attendants of more severe cases of the disease; the appetite is generally impaired; the thirst is considerable; the tongue is sometimes furred, occasionally natural, and the pulse is little, if at all, quickened or affected with respect to its force. The mean duration of this slight form of the disease is from seven to eight days; it may be said to be never fatal, but it not unfrequently lays the foundation of chronic dysentery, and often leaves such a tenderness of the bowels as renders them more prone than before to morbid action from cold or other causes. We should presume that the inflammation in such a case as this was slight in degree, and limited to the rectum and inferior portion of the colon.

A more intense form of the disease than that which has just been described, will be found of frequent occurrence when dysentery is prevailing epidemically. This more severe disease may be preceded by diarrhœa, which we have observed to be a very general precursor of dysentery in whatever climate we have witnessed it; or it may occur without this premonitory symptom. Occasionally a well-marked rigor, followed speedily by febrile heat, introduces the disease; whilst, in other cases, the first symptom is pain in the bowels, to which the mucous stools characteristic of dysentery in a short time succeed. In many instances some slight derangement of the stomach and bowels, indicated by flatulency, costiveness, inappetency, nausea, and occasionally vomiting, is experienced for some days before the attack. When the disease is fully formed, the characteristic mucous or muco-sanguinolent stools are passed very frequently, with great pain, an extreme degree of straining, and a feeling as if the viscera themselves were about to be discharged. Feculent stools occasionally intervene between the dysenteric discharges, and pure blood is sometimes voided in considerable quantity, especially in an advanced stage of the disease. After the disorder has subsisted some days, it is not unusual for the patient to void portions of a substance resembling suet, tallow, or flesh. A sense of heat, or, as the patients express it, burning at the anus, extending thence up the rectum, and which becomes excessive when there is a call to empty the bowels, is much complained of. When fever has occurred from the commencement of the disease, it of course subsists throughout its progress; and in cases in which it has not existed from the first, it usually arises when the intestinal disorder has become so fully formed as we are now describing it to be. There is a warm skin; a hard, generally frequent and small pulse; the tongue is either covered with a white mucous coat, or it is dark and dry; there is great prostration of strength, and the urine is scanty, high-coloured, and is passed with pain and difficulty. The griping which precedes each evacuation is very distressing throughout the disease; but only in an advanced stage, and in a case which has held its course uninfluenced, at least beneficially, by treatment, is there much if any permanent pain in the abdomen. When it occurs, it is generally situated in the hypogastric region, and is increased by pressure. Its presence, especially if it is accompanied by fulness and ten-

sion of the abdomen, may be generally considered as a bad omen, as indicating that the inflammation has extended to the exterior tunic of the bowel. Dyspnœa is frequently observed to co-exist with the symptoms, denoting that the peritoneal surface of the intestines is affected. Throughout the disease there is loathing of all solid food, and the thirst is great, sometimes intense; and it is attended with this distressing circumstance to the patient, that in many cases everything which is taken to allay it produces tormina, and an instantaneous and irresistible impulse to go to stool.

Should no relief be afforded by the remedies employed, the prostration of strength becomes great; the pulse feeble, with coldness of the extremities; the tongue either furred and brown, or glazed, red, and aphthous; the discharges from the intestines are dark and offensive; the mind is low and desponding; hiccough is an occasional symptom, and death sometimes takes place in a period varying from a fortnight to three weeks from the commencement of the attack. But much more frequently, even in bad cases, some mitigation at least of symptoms is obtained, and the disease degenerates into a chronic form.

Restoration to health may be expected when there is diminution of pain in the abdomen, of tenesmus, and of the frequency of the discharges, and especially if, instead of the mucous or muco-sanguinolent dejections, the stools become natural. An abatement of the febrile symptoms and thirst, and a return of appetite, are favourable signs; but all favourable symptoms are to a certain extent fallacious, for after a truce of a few days we may discover that we have that insidious and slowly-wasting disease, chronic dysentery, to combat.

This description, which comprises the two extremes of the disease as it has fallen to our lot to observe it in Europe, is drawn from personal observation. For an account of dysentery as it occurs between the tropics, we must be indebted to the able men who have witnessed its ravages in those regions.

*Tropical Dysentery.*—The following is Sir G. Ballingall's description of tropical dysentery, or, as he very properly terms it, colonitis.

"The form of flux now under consideration commences in general with much of the appearance of a common diarrhœa; frequent and unseasonable calls to stool, with an irresistible inclination to strain over it. The evacuations are generally copious, of a fluid consistence, without any peculiar fœtor; sometimes streaked with blood, and at other times a small quantity of blood is voided in a separate form, unmixed with the fecal matter. The pulse, in this stage of the disease, is seldom altered; the heat of the skin is not perceptibly increased, and the tongue is frequently but little changed in its appearance. There is always a great prostration of strength and depression of spirits; the former symptom being always strongly dwelt upon by the patient; the appetite is indifferent, and the thirst urgent. To these symptoms succeed a fixed pain in the hypogastrium, more or less acute; the pain extending to, and peculiarly urgent in, one or both ileac regions, and sometimes to be traced along the whole course of the colon, with a sense of fulness, tension, and tenderness upon pressure; and on applying the hand

to the surface of the abdomen, a preternatural degree of heat is frequently perceptible in the integuments. The evacuations now become more frequent and less copious; they consist chiefly of blood and mucus, or are composed of a peculiar bloody serum, which has been very aptly compared to water in which beef has been washed or macerated. A suppression of urine and distressing tenesmus now become urgent symptoms; the indifference to solid food increases, while there is an uncontrollable desire for liquids, particularly cold water, which the patient prefers to any drink that may be offered to him, and from which he expresses his inability to refrain, though prepossessed with the idea of its being injurious. The tongue is now generally white and furred; sometimes, however, exhibiting a florid, smooth, and glassy appearance, with a tremulous motion when thrust out; the skin is either parching hot, so as to render it even painful to retain the hand in contact with it, or covered with profuse perspiration, inasmuch that it may often be observed standing in large drops on the surface; the pulse is still frequently but little affected; sometimes, however, it assumes a febrile quickness, without any other remarkable feature; at other times it will be found without any increase of velocity, but full and bounding, with a peculiar thrilling sensation under the fingers. This state of the pulse, whenever it takes place, always denotes extreme danger, and shows that the disease is rapidly hurrying on to the final stage, in which the lassitude and dejection so conspicuous throughout its course are now converted into the utmost degree of anxiety, depression, and fear of death. The patient generally shows an inclination to dwell upon symptoms which to a spectator would appear of minor importance. He evinces the greatest reluctance to part with his medical attendant, though fully sensible how unavailing the efforts of medicine are likely to prove. The discharges by stool, which are frequently involuntary, are now accompanied with the most intolerable fetor; they are frequently mixed with shreds of membrane, and quantities of purulent matter; a protrusion of the gut, forming a complete procidentia ani, takes place; and cases are not wanting where a portion of the inner coat of the intestines amounting to some inches has been thrown off in a state of mortification." (Observations on Dysentery, p. 49.) It is needless to say what must be the result of such a case as this, unless it is efficiently succoured in an early stage.

**Diagnosis.**—The only diseases with which dysentery can possibly be confounded are cholera, hemorrhoidal flux, and diarrhœa.

The rapidity of the march of cholera, compared with the long duration of dysentery, is alone an important ground of distinction between them. Cholera occasionally ceases in twenty-four hours, and perhaps never lasts beyond a week; whilst the mean duration of dysentery is probably about a fortnight, and many cases endure for months. Vomiting is a uniform attendant of cholera, and is seldom observed in dysentery; the purging, during a considerable part of the course of dysentery, is mucous or muco-sanguinolent, whilst its prevailing character in cholera is bilious. Tenesmus is a most distressing symptom of dysentery,

but in cholera it is generally absent. In cholera the alvine discharges are copious, and are passed with violence; the very reverse is the case in dysentery, and the former disease is attended with spasms of the extremities, which are not perceived in the latter.

The tumours at the margin of the anus; the blood flowing from the commencement of the disease unmixd with mucus; the comparative absence of tenesmus; the freedom from abdominal pain; and the solid nature of the feculent discharges, which are observed in hemorrhoids, will secure us from confounding this disease with dysentery.

The distinction between dysentery and diarrhœa is easily drawn, in the more advanced stage of the former disease, from the mucous and sanguinolent condition of the alvine discharges; but the testimony of the writer must be added to that of Sir James M'Grigor and many others in proof of its extreme difficulty, in many cases, in an early stage. If it is then to be found at all, it must be sought in the character of the prevailing epidemic rather than in that of any individual case submitted to our observation. We believe that the pathological condition in dysentery, and in cases of severe diarrhœa, is in its nature the same; but that the inflammation of the lining of the digestive canal is more intense and enduring in the former than in the latter disease. In both cases, the first effect of this inflammation is the rapid expulsion of the ordinary contents of the intestinal canal; but the inflammation existing in dysentery remains after the canal is entirely emptied, and gives rise to those secretions from the lining membrane which constitute the discharges characteristic of the disease. In certain cases, those unpreceded by diarrhœa, the site of the inflammation in the lower part of the bowels seems to have the effect of retaining the natural contents of the canal, and of causing, from the first, evacuations consisting merely of matters secreted from the bowels.

From the description given of epidemic choleric fever, (see CHOLERA,) it will be manifest that from the moment the choleric stage is fully formed, no confusion can arise between this disease and dysentery. The spasms, serous discharges, and early collapse of the former disease, are extremely distinctive. But in the incipient stage of the two disorders, some difficulty might be experienced, which would, however, be dispelled by a reference to the character of the prevailing epidemic.

In this view of the diagnosis of intestinal affections attended with increased discharge, it is impossible not to be struck with the strong relation which in their rudimental stage they generally bear to each other—a relation which cannot but lead to the suspicion, that, however widely different in character and danger they may be when fully formed, the primary pathological condition is, in all, if not identical, certainly closely analogous.

**Chronic Dysentery.**—This may be considered as almost a more distressing termination of the acute form than death itself, for recoveries from it are rare, and it is fatal after an amount of protracted suffering which is extreme. The fever which attended the acute form subsides, and a temporary recruiting of strength and appetite is

experienced, but this truce from distress proves deceptive. The patient occasionally feels sharp pains of the bowels, with frequent stools, consisting of food apparently little changed by the process of digestion, mixed with slight streaks of blood: these symptoms may subside, and continue to recur at intervals, either from some manifest imprudence in regimen, or without any assignable cause, until extensive disorganization of the intestine takes place. The stools are then mucous and bloody, sometimes mixed with purulent matter; or such dejections as these alternate with discharges of sanies, or of offensive, ill-digested fæces, the number of evacuations varying from three or four to seven or eight in the day. The abdomen at the same time feels full and hard, without being very painful on pressure; the urine is high-coloured, and is passed with pain. The patient, when in bed, lies on his side, with the body much curved, and the lower limbs in the position of extreme flexion on the abdomen, so as to relax its muscles as much as possible. The pulse is feeble, intermitting, and generally slow, excepting towards evening, when some degree of fever occurs. The tongue is often bright and glossy; the skin is cold, sallow, dry and rough; the lips appear exanguis; emaciation proceeds rapidly; the feet and legs become œdematous, and ascites occasionally takes place; the patient sometimes becomes jaundiced; and finally, after the lapse of weeks or months, he sinks from irritation and exhaustion.

The odour of persons suffering under this disease is peculiar, and the same may be occasionally observed in the acute disease: no description could convey an idea of it to one who had not experienced it, but if once recognized, it cannot be forgotten; it is very offensive, and at the same time acid. It is independent of that of the matter ejected from the bowels.

Acute dysentery occasionally leaves the bowels in a condition less decidedly morbid than that just described, and one from which the patient generally recovers, but after a considerable lapse of time, perhaps of years. This condition is indicated by attacks of diarrhœa, commonly of the lienteric character, recurring at intervals of three or four weeks, and lasting for a few days; during the attacks the dysenteric odour is perceptible about the person of the patient.

*Complications of Dysentery.*—This disease is found combined with fevers, that is, instead of the pyrexia symptomatic of the local affection, some form of idiopathic fever exists in conjunction with dysentery; and if the fever is a contagious one, the two may be communicable together. Knowing as we do the proclivity of fevers to affect the intestinal lining, it cannot be matter of surprise that the large intestines should be occasionally the seat of such affection. There are other diseases, too, with which it is occasionally found combined.

The complication with typhus occurs under the operation of debilitating causes, such as want of food; and where numbers of persons being accumulated in a space proportionately small, proper ventilation and cleanliness are impracticable.

From these causes it has frequently proved more fatal to the garrisons of besieged towns than the

assaults of the enemy. It is characterized by a remarkable stupor, resembling that of a drunken man; by headach, vertigo, and delirium; the eyes are dull and very sensible of the impression of light; on some day between the fourth and the sixth day, a miliary or petechial eruption often appears on the neck, breast, and arms; the tongue, teeth, and gums are covered with dark sordes, and the pulse is frequent and small, or, when the danger is imminent, intermitting. The dejections are frequent, scanty, composed of mucus mixed with dark-coloured blood, and of an extreme fætor; the urine is high-coloured, as if stained with blood; nasal hemorrhage is not unfrequent, but it does not prove critical; the usual colic pains of dysentery are severe during the first four or five days; then they abate, and are again increased about the ninth or eleventh day, when a diarrhœal discharge comes on which frequently destroys the patient rapidly. When the case is fatal, death generally occurs from the ninth to the thirteenth day, but sometimes as early as from the third to the seventh.

Dysentery occasionally complicates the early stage of intermittent fever, and in this stage it may be found either during the paroxysm only, or, which is much more frequently the case, as a permanent disease associated with the ague. But its existence at the commencement of intermittents is very rare in comparison with its occurrence at a more advanced period, when disorganization of the liver and other abdominal viscera has resulted from the long continuance of the disease. Its supervention in the advanced stage of ague constitutes a melancholy complication, and is very frequently accompanied or followed by general dropsy; the patient lingering in much suffering until released by death. (See *INTERMITTENT FEVER*.)

Pathological researches have proved the complication with disease of the liver to be much less frequent than was supposed; yet there seems no doubt that, in a form of dysentery occasionally met with in warm climates, there is such a complication. The affection of the bowels commences in the form of diarrhœa; the stools are variously coloured, black, green, or deep yellow; they are preceded by considerable griping, felt principally about the umbilicus; they are frothy, accompanied by much flatus, and cause considerable scalding or excoriation about the anus. After a few days they become white and mucous, with an occasional admixture of imperfectly digested aliment. Throughout the disease, there is inappetency, with nausea, intense thirst, a yellow fur on the tongue, great oppression in the epigastrium, and a frequent pulse. It is a slow disease, lasting for weeks or months; and in its progress great emaciation, hiccup, and bilious vomiting, are superadded to the other symptoms. This form of dysentery, which is sometimes called hepatic flux, may terminate in health, in incurable disease of the bowels, or in abscess of the liver.

The following graphic sketch of a form of dysentery more intense than the foregoing is drawn by an experienced observer of the diseases of warm climates. According to the views of the writer, which are most probably accurate, it should be referred to the complication of dysentery with

hepatic affection which we are at present describing.

"The patient is at first languid, and loses at the same time his appetite and hilarity of mind. Sometimes he complains of pain in the region of the liver, increased by pressure, and in some degree relieved by the expulsion of flatus from the stomach; but this pain is very trifling, or at least much more slight than might be expected from the condition of the liver as discovered after death. The presence of this symptom denotes the true character of the disease; but in many cases it is entirely wanting, and hence the greater obscurity. In many cases the most acute observer can discover no sign of bad health, but a white tongue and a pulse more frequent than usual.

"Matters remain in this state during a period varying from four to eight days, and the inexperienced practitioner apprehends little danger; but in this respect he is deceived; for an insidious fever depresses the patient by almost imperceptible degrees, till the actual symptoms of dysentery, namely, tenesmus and very frequent alvine discharges, display themselves with great violence. These symptoms are accompanied by ardent fever, delirium, oleaginous sweat, febrile anxiety, and urgent thirst, whilst the tongue is covered with a yellow fur, which is converted towards the close of the disease into a permanent dark crust. A large quantity of green, bilious, and sanguineous matter flows from the bowels, and finally convinces the medical attendant that the morbid condition of the liver and bile is the exciting cause of the flux. There is not much pain in the bowels in this stage of the disease; but the tenesmus is most distressing, and occasionally protrudes a portion of the rectum from the anus. Subsultus tendinum, hiccup, and cold sweats take place; and, unless relief is afforded before the disease reaches this stage, death speedily ensues." (*De Dysenteria Regionum Calidarum*. Archibaldo Robertson Auctore. Edin. 1817).

**Pathological Appearances.**—These vary according to the period of death and the nature of the case. If dysentery prove fatal in an early stage, the appearances are those of inflammation simply, or of inflammation and gangrene of the mucous membrane of the large intestines, with few or no traces of ulceration. If at a more advanced period, the other coats of the bowels are found to participate in the disease, and numerous and extensive ulcers are discovered. In inflammation, the external appearance of the bowel is healthy; but, on opening it, portions of its mucous membrane throughout the whole extent of the colon and rectum, and occasionally some part of the small intestines, are found of a bright red or brownish colour, and sensibly elevated above the level of the more healthy parts which are interposed between them. These inflamed portions are sometimes covered with a puriform, sanguineous, or sanious secretion, which gives them the appearance of ulceration; but if this is scraped off with the back of a scalpel, and the part is washed, the surface is found unbroken. False membrane is sometimes found deposited on the mucous coat. Dr. O'Brien describes it as occurring both in the large and small intestines, but as being most frequent and

remarkable in the colon and rectum. In some cases, he informs us, it occurred in patches, but in others the mucous membrane was covered by a uniform layer of white lymph. (*Transactions of King and Queen's Colleges*, vol. v.) Gangrene is denoted by blackness or lividity, and morbid softness of the membrane, the muscular coat occasionally partaking of the softness; and in some instances by vesicles full of a fetid fluid.

In cases which have terminated fatally in a more chronic stage, there is thickening of the tunics of the intestine, and the bowel is contracted in diameter and ulcerated. The ulcers are diffuse or follicular. The former may be of the size of a sixpence or a shilling, or an extensive portion of the membrane may be in a state of almost continued ulceration, the diseased surface being varied by portions in a state of red fungous elevation, running irregularly over it, and separating the ulcerated spaces from each other. The follicular ulcers are of the size of split peas; their concavity is lined with pus, and their edge is surrounded by a red circle. The follicles are occasionally found in a state of inflammation, having a tubercular appearance, compared to small-pox. The ulceration occasionally perforates the coats of the intestine so as to allow its contents to escape into the cavity of the abdomen. This accident and its consequences deserve separate consideration. (See *PERFORATION*.) Adhesions of the peritoneal surface to the adjacent viscera, and serous effusion into the cavity of the abdomen from the extension of inflammation to the exterior tunic of the intestines, are not unusual occurrences.

Other viscera, beside the bowels, are occasionally found to show traces of disease. The mesenteric glands are sometimes enlarged and inflamed, and the omentum is described by Dr. Jackson as being in some cases dry and shrivelled, in others gangrenous, and occasionally forming a new and fleshy-looking substance, which confines the intestine in such a manner as to obstruct its canal. (*A Sketch of Febrile Diseases*, by Robert Jackson, M.D., Stockton and London, 1817, p. 439.) The liver has been supposed to be generally affected in dysentery, and it is occasionally found small and indurated or enlarged, and at the same time of a firmer consistence than natural, or an abscess has been found in it in that form of the disease called hepatic flux; but pathological researches have proved that changes in its structure are much less frequent than was imagined, and by no means essential to dysentery. Even in cases of this disease in which this organ is functionally affected during life, or in which researches after death show that its structure has undergone a change, (and the instances where this latter occurrence is discovered bear a very small proportion indeed to the whole amount of examples of fatal dysentery;) there is great reason to think that the irritation is rather propagated from the intestinal canal to the liver, than that the reverse order of causation takes place. There is no organ of the body of which the influence in generating disease has been so much overrated by medical men as the liver, occasionally perhaps from mere carelessness, but too often, we apprehend, from a not very creditable wish to run with

the current of popular opinion, which throughout Great Britain and her dependences is strangely favourable to hepatic and bilious doctrines.

**Causes.**—Dysentery is generally most prevalent during the latter end of summer and autumn, when the alterations of temperature are sudden, and especially when there is a considerable discrepancy between the heat of the day and night; but there is no season of the year in which it is not found occasionally to make its attacks, provided the body be exposed to the cause peculiarly favourable to its production, cold or chill after comparative warmth. It is much more prevalent in the warmer latitudes than in temperate climates; probably in some degree from the circumstance, that in the former situation the heat of the day is followed by great comparative cold at night, the chilling effect of which is aided by the heavy dews which are so general in the warmer regions of the earth. The operation of the same cause is manifested in the case of soldiers, who are frequently attacked in numbers after a night-encampment or bivouac on damp ground.

Unwholesome food, the abuse of spirituous liquors, and the drinking of bad wine, bring on attacks of the disease in climates and situations where it prevails; but indulgence in fruit, which is often assigned as its cause, does not appear to have such an effect.

Malaria is supposed to be a cause of dysentery, and there is reason to think the supposition correct. The disease occurs in the climates, situations, and seasons favourable to the production of periodic fevers; it is occasionally combined with them, and appears to succeed or supplant them, as though it were owing to a continuance of the operation of the febrile cause, modified in its nature or influenced in its effect by extrinsic circumstances. The analogy between dysentery and other forms of bowel complaints and such fevers has struck the eye of observers from Sydenham to Jackson. It is difficult to assign to the first-mentioned causes, cold and bad diet, and to malaria, their respective share in the production of the disease. It is probable that sporadic cases are frequently owing to the former exclusively, and that they may co-operate in producing attacks of the disease when it is prevailing epidemically; for instance, malaria having been applied, exposure to cold or dietetic errors may immediately bring on an attack.

The discrepancy of testimony as to the contagious nature of this disease is extreme; but were the question one which the preponderance of great names could decide, it would probably be answered in the affirmative. So general was the belief in its contagious nature some years ago, that contagious pyrexia is inserted among the characteristics of the disease in Cullen's Nosology, as if it were an acknowledged incontrovertible doctrine. But in the present day we believe there is scarcely a medical man of much experience in the disease who believes it to be contagious; and the writer has never seen a single case which he had the least reason to attribute to such a cause. The conflict of opinion on this point is perhaps to be explained by certain authors having seen many cases of dysentery complicated with typhus, and by their having ascribed

to the disease, generally, that which is true only of one of its complications.

**Treatment of Acute Dysentery.**—The nature of the disease being ascertained, the practice to be pursued becomes sufficiently obvious. Bloodletting naturally presents itself as one means of subduing the inflammation; and if the constitution sympathises with the local affection, so that there is general fever, with a warm skin and a frequent and sharp pulse, blood should be taken freely from the arm. We should not rely upon general bleeding as the sole mode of depletion in the disease, for experience teaches us that the inflammation of mucous membranes is less amenable to this remedy than that of most tissues; but it should be followed by local bleeding by means of leeches; and in the milder order of cases this may altogether supersede general depletion. Twenty or thirty leeches should be applied along the course of the colon, or to any point of the abdomen where pain is felt, the parts being subsequently covered with a hot poultice. The repetition of leeches must of course depend upon the intensity and duration of the disease, and the degree of relief afforded by the first application. Should griping, purging, and particularly fixed abdominal pain continue, they may be repeated on the following day, or each succeeding day, to the third or fourth time, if the circumstances mentioned indicate the propriety of the repetition, their number in the later applications being regulated by the necessity of the case and the strength of the patient. It should be remarked, however, that the first application, if vigorous, frequently affords so much relief, that, by the aid of internal medicine, the disorder proceeds thenceforward very steadily to recovery. Hot fomentations and the warm bath will be found serviceable after the bleeding, and subsequently the abdomen may be blistered with benefit.

Purgatives are generally administered; and, during a considerable period when the retention of feculent matter in the cells of the colon was erroneously supposed to constitute the very essence of the disease, they were principally depended upon by some practitioners for its cure; and though the more correct views at present entertained may seem to forbid their employment, experience teaches us that to unload the bowels, when requisite, with gentle laxatives, is not only safe but beneficial. Were the writer to digress into a question of general therapeutics, but one connected with the present subject, he would remark that though laxatives are found prejudicial in neuralgic irritation of the intestinal canal, he has never observed injurious effects from their moderate and judicious employment in inflammation of its mucous lining; and that he has detected the most extensive lesions of this membrane, where the practitioner had rigidly abstained from them. It is desirable, however, that the abuses which heretofore existed, regarding their employment in dysentery, should not be resuscitated, and on this account it appears advisable to specify the sole circumstances under which they should be administered in this disease, and the precautions this administration requires.

In every case of dysentery, the first remedial measure should be directed to subduing the essen-

tial disease, the intestinal inflammation; the primary and paramount means, therefore, are the general or local bleeding, or both, as the circumstances of the case may require. In that form of the disease which is unpreceded by diarrhœa, a dose of castor-oil, sufficient to expel the matters lodged in the intestines, may be given after a little respite from suffering has been obtained by bleeding; and should its operation be tardy, it may be accelerated by a mild emollient enema. In that more frequent form of the disease which has diarrhœa as a precursory symptom, purgatives should by no means be employed early; but in any form of dysentery, should a considerable period have elapsed without a feculent discharge, a mild laxative will be advisable, for the retained matters are generally in a morbid condition, and can scarcely fail to be a greater source of irritation to the inflamed membrane than the operation of a gentle laxative. The repetition of medicine of this kind will of course depend on the circumstances of the case; should the alvine discharges become feculent and copious, it need not be repeated. No more proper laxative can be selected than the oleum ricini, aided in its operation by a mild, tepid, and emollient enema. Some practitioners think favourably of a solution of neutral salts with which a proportion of tartarized antimony is combined; but it seems doubtful whether the irritating effect of the salt on the intestines would not counterbalance the benefit likely to accrue from the diaphoretic action of the antimony.

Mercury is so powerful a subsidiary of general and local bleeding in the cure of inflammation, that we should naturally expect benefit from it in this disease; and experience proves its prudent employment to be of great service. It might be objected to on the same ground as purgatives, the dread of an irritating effect from it on the inflamed intestine; but the result of its employment, our only safe guide, shows the apprehension to be erroneous, provided the medicine be properly administered. It is a remedy more generally applicable to dysentery in warm latitudes than in this country; but if employed with prudence, and merely as subsidiary to the general or local bleeding, or both, advantage will be derived from it wheresoever the disease may be prevailing. A grain or a grain and a half of calomel, combined with from five to ten grains of Dover's powder, or half a grain of opium; or five grains of hydragyrus cum cretâ, likewise combined with the opiate; may in this country be administered at intervals of four hours, the period being lengthened when the symptoms begin to abate. It is not necessary to excite pyalism, although this is a contingency from which no evil result need be apprehended, provided the medical attendant be sufficiently watchful of the effect of the remedy to prevent its being excessive. In warmer climates, the same dose of mercury, combined with a smaller proportion of Dover's powder, or a grain of ipecacuanha, may be given every hour or two till some effect is produced on the disease or the system. In our Indian settlements the practice is much bolder than this, calomel being administered in doses of a scruple. Mr. Annesley gives such a dose nightly, followed by an oily or a saline purgative in the morning, till the dejections become

natural and healthy, (Sketches of the Diseases of India, p. 417;) and calomel in such doses is a familiar remedy with British physicians in tropical climates.

Diaphoretic medicines are employed by many medical men in dysentery. The cerated glass of antimony, which was a favourite remedy with Sir John Pringle and others, probably owed great part of its influence over the disease to its power of exciting perspiration; and the combination which has already been mentioned, that of a mercurial preparation with Dover's powder, perhaps derives part of its very great utility from the same property. Ipecacuanha alone is a valuable medicine of this class. It may be given in large doses in the form of pills without exciting vomiting, as in the manner recommended by Mr. Twining in the Calcutta Transactions. By combining it with extract of gentian he exhibits as much as six grains, which he repeats at intervals; and, as he assures us, with an excellent effect. A decoction of three drachms of the root, boiled in a quart of water down to a pint, administered in portions of three or four ounces, as an enema, and repeated once or twice in the day, we have often found to have the effect of allaying irritation and tenesmus, and to be generally beneficial. The same medicine is frequently combined with calomel, or other mercurial preparations, with considerable improvement of the efficacy of both. Emetics are favourites with some practitioners, but the benefit to be derived from them is much more certainly and easily attained by nauseating or diaphoretic doses of ipecacuanha.

Tenesmus is frequently a distressing symptom. Of course effectual relief can be afforded only by the general process for subduing the disease; but it may be allayed by anodyne enemata, of which a solution of three or four grains of opium in a small quantity, not more than two ounces, of starch mucilage, constitutes a very good one. Dr. Abercrombie recommends injections of lime-water, at first diluted with milk or thin arrow-root, with the addition of an opiate. It should be impressed on the minds of junior practitioners that enemata administered with the view of allaying tenesmus should be small, for this affection is aggravated by distending the lower portion of the intestinal canal with bulky fluids. Mild emollient clysters have already been recommended as adjuvants to the oleum ricini when there is retention of feculent matter in the intestines; but it should be understood that their employment in these cases is admissible only when the irritation of the inferior portion of the canal is not extreme. We have met with instances in which even the introduction of the pipe could not be borne. In such cases as these, tenesmus and irritation may be allayed by opium, Dover's powder, a dose of laudanum, or by opiates combined with infusion of cusparia or balsam of copaiba, administered by the mouth.

Dr. Cheyne, whose practice in the dysentery of this country has been very extensive, thinks highly of the power of opium in its cure, and gives the following summary of his experience of its efficacy and that of other remedies. The mode of treatment he found most generally useful was bloodletting, followed by calomel and opium, and

this by balsam of copaiba and farinaceous diet; and he says, "were the same cases again to be placed under my care, I would not hesitate to give opium in doses of four or five grains, as it was the opium chiefly that seemed to arrest the progress of the inflammation; and whatever in such a case procured respite to the patient from agony, sometimes proved of permanent benefit." (Dublin Hospital Reports, vol. iii.) This testimony, proceeding from such a quarter, should have great weight. The concluding clause contains a truth of much importance, and one applicable to many diseases besides dysentery.

[Dr. Christison expresses the belief, that the cure of epidemic dysentery may often be effected by opium alone, begun early and given boldly. In one epidemic, it was prescribed at once in the dose of one, two, or three grains every six, four, or three hours, according to the urgency of the symptoms, until signs of its narcotic action began to display themselves; and in this way sometimes twenty and even thirty grains were given in the first twenty-four hours. In several cases, where the treatment was commenced not later than the close of the second day, the force of the disease was at once completely broken, and the only remedies needed afterwards were the continuance of the opium in diminished doses, and restricting the patient to pulpy solids as diet. The writer has often seen the excellent effects of opium in this as well as in other inflammations, given in sedative doses; but caution has to be used that it be not pushed too far.]

Swathing the abdomen with flannel, so applied as not to press painfully, is useful as a means of keeping the temperature uniform. Should abdominal pain require relief, hot fomentations may be frequently and freely resorted to. If the anus be inflamed or excoriated, it should be bathed with goulard water; and it may be protected from the acrimony of the discharges by being anointed with unguentum cetacei, or wax and oil.

The diet throughout the disease should be mild and light, consisting of arrow-root, milk, simply, or with gum acacia dissolved in it, rice or barley-water, and mucilaginous and bland matters of this description; they should be given in small quantities at a time, and the whole amount of what is taken should be small.

**Treatment of Chronic Dysentery.**—Our indications here are much more perplexed, and our difficulties much greater, than in the acute form of the disease. That intestinal ulcers occasionally heal has been proved by Dr. Troilet, (*Journal Général de Médecine*); and Dr. Latham, in his account of the disease which prevailed in the Penitentiary at Milbank, has given an excellent description of intestinal ulcers in the progress of reparation: hence we should not utterly despair of success in this very intractable malady. As in most diseases which are but little amenable to our art, the remedies proposed are very various. Those which deserve the most confidence are small doses of hydrargyrum cum cretâ or calomel with Dover's powder, or the same mercurial preparations with opium and ipecacuan; lime-water; vegetable astringents and bitters, as kino, catechu, cusparia, quassia and logwood; nitric acid; opium, balsam of copaiba or tolu; or various combi-

nations of these remedies, as a strong decoction of cusparia with nitric acid and laudanum, recommended by Dr. Abercrombie. The late Dr. Jackson, whose experience of this form of disease was very extensive, placed much reliance on small general bleedings, repeated at intervals of a week; but in a disease attended with so much debility as this, very moderate local bleeding from the integuments of the abdomen, and the application of blisters to the same parts, appear to be safer methods of accomplishing the object to be attained. Moderately stimulating and oleaginous frictions of the abdomen, the part being subsequently swathed with flannel, are occasionally found useful; and the warm salt-water bath is soothing to the patient, and generally beneficial to the disease. Powdered charcoal, combined with powder of ipecacuan and rhubarb, has been found advantageous; and Dr. Abercrombie speaks favourably of a combination of the same substance with Dover's powder. The writer has found considerable temporary benefit in this distressing affection from the sulphate of copper, administered in the manner recommended by Dr. Granville in various chronic affections of the bowels. It is given in doses of half a grain with an equal quantity of opium; and is gradually increased, if necessary, sometimes to the extent of three grains, with half-a-grain or a grain of opium three times a day. Where there is reason to suppose that the lower part of the intestinal canal is the seat of ulceration, various injections are employed with advantage. A weak solution of acetate of lead or white vitriol has the effect of allaying irritation; whilst a solution of blue vitriol, or one of corrosive sublimate in lime-water, excites foul and sluggish ulcers to healthy action, and in some cases has appeared to aid materially in effecting a permanent cure. These injections should not consist of more than two or three ounces of fluid, for great irritation is produced under the circumstances mentioned by distending the canal by large enemata.

[The various remedies recommended in diarrhœa (q. v.) are equally appropriate in the affection under consideration.]

The diet, throughout the disease, should consist of the mildest and most bland farinaceous food, taken in small quantity, solid animal food and all stimulating matters being rigidly forbidden. Solid food, in any considerable quantity, must be injurious as a more mechanical irritant in that condition of the intestines which beyond a doubt exists in chronic dysentery; whilst liquid freely taken excites griping, passes rapidly through the bowels, and must tend to disturb that reparatory process which it should be our object to encourage. If the disease have commenced in a district where dysentery is endemic, change of air is a remedy of first importance, and one without which all other means will often prove nugatory. A sea voyage has frequently proved very advantageous.

The treatment to be adopted in dysentery, complicated with *idiopathic fevers*, will be gathered from the rules contained in this article, and in the articles on continued and periodic fever. The combination with liver disease, the *hepatic flux* of Ballingall, and others, requires mercurial treatment by means of blue-pill, calomel and opium, or inunction, till pyalism is induced; and this

unless the exhaustion of the patient forbid it, is to be kept up till the discharges assume a healthy appearance. Laxatives are occasionally requisite, and of these castor-oil is the most proper. The warm-bath, sudorifics, blisters, and bandaging the abdomen with flannel, are as important as in the treatment of the uncomplicated disease; and should the tenesmus be distressing, it may be allayed by any of the forms of anodyne enemata recommended in that disorder.

JOSEPH BROWN.

**DYSMENORRHŒA**, (from *δύς*, *ægre*; *μήνες*, *menses*; *ῥέω*, *fluo*;) *painful or difficult menstruation*.—This disease is important from its occasional extreme obstinacy; from the great suffering which it produces, and from the contrariety of opinion which prevails as to its nature, and the treatment required for its relief. In healthy menstruation there is often no warning whatever of the period; more generally there is some degree of discomfort, consisting of a sensation of weight and fulness about the pelvis, with a bearing down and aching of the thighs, but usually the suffering is so slight as not to call for medical aid; in dysmenorrhœa, however, the menstrual period is accompanied with such acute pain and suffering, and is looked forward to with such apprehension, that the patient is eagerly inclined to seek for relief, and is but too often driven from one remedy to another with but trifling advantage.

The time at which the pain comes on varies in different cases. In many the pain precedes the discharge, or else the discharge is exceedingly scanty as long as the pain lasts; but as the quantity increases to a full flow, a subsidence of the suffering takes place; in these cases the pain will last only a few hours. In other instances the discharge is more profuse than natural during the whole continuance of the pain, is apparently expelled in gushes, and is then usually mixed with coagulated blood. In a few more rare cases the pain will only occur in the latter part of the menstrual period, accompanied either with a diminution or an increase of the flow, and ceasing only after every vestige of the discharge has passed off.

All these varieties will be found in practice, though in the histories of this disease some have been often omitted, and most authors have described the pain as occurring only at the onset, and ceasing when the full and free evacuation takes place.

The pain often resembles the grinding pains of the first stage of labour, and is similarly in paroxysms of short duration and frequent recurrence. There is also, in the intervals, a constant aching pain down the legs, with a dragging sensation in the back and loins; there is sometimes, also, a sensation of bearing down in the pelvis, with even an actual lowering of the uterus. All these pains will vary in degree; for in some severe cases the paroxysms have been so violent that the patient has rolled on the bed or the floor with agony, and, in a few instances, the writer of this article has noticed severe convulsions of the character of tetanus, even amounting to regular opisthotonos. The expulsion of a membranous substance has been observed in dysmenorrhœa by Morgagni, (Epist. 48, art. 12,) who described it

as generally consisting of a small bag, containing a fluid, on which account it was usually mistaken at that time for a very early abortion. More particular notice was attracted to this peculiarity in modern days by the late Dr. Denman, who satisfactorily established the fact that the membrane was expelled at least as frequently in single as in married women, and that it had the appearance of a triangular cast of the cavity of the uterus, having an exact resemblance to the membrana decidua. It would seem that where a bag containing a fluid was really discovered, it must have been an ovum, at an early period of conception, particularly as such women are very liable to miscarry. Dr. Denman was of opinion that this membrane, although often not noticed, was expelled in every case of dysmenorrhœa. That he was wrong in this conjecture is now well known, as, though occasionally met with, it is by no means common, although there are often substances perceived which at first sight resemble it, but which consist merely of coagula of blood, with the colouring matter separated. From the supposition that the membrane is *always* expelled, and that it consists of coagulable lymph exuded from the lining of the uterus, necessarily resulting from inflammatory action, has arisen a very faulty opinion of the nature of the disease, and a most mistaken and pernicious mode of treatment, *when universally applied*.

Dysmenorrhœa may arise at any period of life at which the menstrual function is performed. It will sometimes exist from the time of puberty and cease upon marriage; in other instances the first attack is immediately after marriage, and lasts till the patient becomes pregnant; in some it does not appear until after child-birth. It has been often stated that no woman can become pregnant whilst this disposition to dysmenorrhœa exists; but this is far from being correct; the error arising from the fact that such patients are particularly liable to abortion at a very early period, which abortions have been supposed to be merely unusually aggravated attacks of the complaint. Nor again, as has been generally considered, is pregnancy a cure for a previously existing dysmenorrhœa, unless by great care and management the first two or three months are safely passed over.

It would appear that the immediate cause of this distressing disease is extreme irritability of the uterus; and as it is well known that great irritation is but a step removed from inflammation, it is very probable that in some cases, where a membrane is expelled, inflammation of a peculiar character may be excited. It does not follow as a certainty that the separation of a cast of fibrine from a mucous surface is the result of decided inflammatory action. Some pathologists have gone so far as to dispute the possibility of pure inflammation arising in a membrane where no blood-vessels are to be found, although they ramify profusely in the sub-mucous tissue. The tubular casts of lymph from the lining of the intestines are often brought on by irritation alone, as by the improper and excessive administration of calomel; and in croup, the fibrinous tube, which is occasionally formed in severe cases, is not found adherent by vascular union to the surface on which it is deposited. Although he does not exactly agree in

these views, it certainly appears to the writer that the pain of dysmenorrhœa is no proof of inflammation, any more than the pain of labour; and it may be stated that generally there is no other sign of inflammation present but pain; that the pulse is merely quickened during the immediate paroxysm, at which time alone the skin is hot or the face flushed; frequently indeed the skin is damp and cold, and the face pallid. On two occasions, where blood was drawn from the arm during the painful period, no buffy coat or contracted cupped surface was found to exist. Although the writer does not deny the occasional existence of inflammation, particularly in plethoric and robust constitutions, yet he believes that in by far the majority of cases acute irritation alone exists. The women most liable to this complaint are those possessing great susceptibility of frame, who are subject to hysterical affections, and who have strong passions and ardent temperaments. Dysmenorrhœa will often occur only at those periods of life when there is great constitutional disturbance, or much mental excitement, as at the early years of menstruation, or shortly after marriage.

[It is affirmed by Dr. Ferguson (*Tweedie's Library of Medicine*, Amer. edit. iii. 305) that sexual intercourse, immediately previous to the expected menstrual flux, has excited the severest forms of the disease.]

**Treatment.**—This has varied according to the view taken of the nature of the disease. Those who consider it to be universally of an inflammatory character, have of course recommended bloodletting, local and general, frequent depleting medicines, and a spare diet. Where the deciduous membrane has been certainly and habitually expelled, it is not improbable but that benefit may be derived by local bloodletting to a moderate extent; but as a general rule, such treatment is not required, and in many instances it has done considerable mischief by the extent to which it has been carried. By the character of the constitutions usually affected, by the spasmodic nature of the pain, and by the success of a very opposite class of remedies, it would appear that the disease is rarely inflammatory, perhaps never purely so, but that it arises from a peculiarly irritable condition of the uterine organs. On this principle the treatment is twofold: 1. to relieve the immediate pain during the menstrual period; 2. to regulate the general health in the intervals. For the first purpose opium is the best remedy, where it can be borne, and particularly when combined with ipecacuanha, and with camphor in doses of four to ten grains. Immediately before the expected attack, the bowels should be opened by a mild purgative or a warm-water injection; the patient might also put the feet in warm water, or sit in a warm hip-bath. At this time should the pulse be full and frequent, the countenance flushed, and general plethora prevail, the local abstraction of blood by cupping on the loins, or by leeches to the pudenda or groins, might be advisable.\* At the onset of the pain, opium (or any of the other

narcotics, if more suitable,) may be given in full doses, combined as before mentioned, and repeated every hour or two according to the effect. Belladonna plasters may be applied to the sacrum; injections of warm mucilage, containing belladonna or opium, may be frequently thrown into the vagina; and, in addition, we may direct suppositories of clysters, containing from one to two grains of opium. Hot fomentations to the pubes, loins, and perineum are also frequently of great service. Ether, assafœtida, and ammonia may be taken at intervals. Hot gin-and-water is a very popular remedy, and will often subdue the pain. These medicines, however, should be cautiously administered, should there be much heat of skin and feverish excitement.

In the intervals of the periods the general health is to be regulated, and the constitution to be strengthened so as to be rendered less irritable. It would be advisable, should the patient be married, that intercourse should be avoided for about a week before the expected attack. In the majority of cases the preparations of iron are the best remedies which can be given, combined so as not to produce too great excitement of the circulation. Equal parts of vinum ferri and the compound spirit of sulphuric ether (3ss to 3i) may be given two or three times a day, or the mistura or pilula ferri composita of the London Pharmacopœia may also be tried. A useful combination is the sulphate of iron, the compound extract of colocynth, and the soap and opium pill, two grains of each. The natural chalybeate waters seem on the whole to be more serviceable than any artificial preparations. Where iron disagrees, some of the other metallic tonics may be of advantage, particularly the zinc. The vegetable tonics do not appear to be of much use; we must except, however, the senega, which Dr. Chapman, of Philadelphia, has confidently recommended, especially in those cases where a membrane has been habitually expelled. He was induced to try this medicine from a supposed analogy between this form of the disease and croup, as regards the formation of fibrine from a mucous surface; he advises four ounces of the decoction to be taken daily. [Experience has not, however, confirmed this view in either one disease or the other.] In obstinate cases a course of mercury has been found the means of cure, particularly when combined with sarsaparilla. Repeated blisters or caustic issues to the sacrum have also been tried, and in some instances successfully. The bowels should be kept open, but not too much so, and the purgatives should not possess an irritating character. Moderate exercise is advisable, but all violent exertions are to be avoided. The diet should be nutritious, but not stimulating. Cold hip-bathing will be found of use, and much benefit will arise from the regular employment, night and morning, of cold-water injections into the vagina, especially if combined with the superacetate of lead. In a few cases there has been a remarkable connection between the existence of this disease and rheumatism in the same person, and the medicines, such as guaiacum and colchicum, given to relieve the rheumatic symptoms, have at the same time cured the dysmenorrhœa. This was accidentally noticed in a case, some years ago, by Dr. Gooch,

\* In the writer's opinion it is only in such cases that bloodletting is desirable; but it is fair to state that many eminent practitioners lay great stress on free and repeated removal of blood in nearly all cases of dysmenorrhœa, from the belief that the pain necessarily denotes inflammation.

with regard to guaiacum, and he consequently was induced to try that medicine where the painful menstruation existed without the rheumatism, and sometimes with success. Further trials, by the writer of this article, have confirmed this observation in several instances, and it is remarkable (since Dr. Gooch's observations were never published) that the same remedy has been highly spoken of by Dr. Dewees, of America, in a recent publication.

[*Mechanical Dysmenorrhœa* is a variety which has been ascribed to the small size of the os uteri, or to a narrowness or stricture in some part of the canal of the cervix. To remove this condition, it has been proposed to introduce a common metallic bougie, of which there are various sizes, from that of the metallic probe upwards. When Dr. Mackintosh published the 4th edition of his *Principles of Pathology and Practice of Physic*, he had treated twenty cases by dilating the os uteri, and had permanently cured eighteen. After that period he had other successful cases; for Dr. Churchill (*Diseases of Females*, 2d Amer. edit. p. 80: Philad. 1843) states that he had employed dilatation in 27 cases, and cured 24, of whom 11 had since borne children. The operation may be performed—the patient lying on the left side—by introducing the index finger of the left hand until it reaches the os uteri, for the purpose of directing the instrument to the part: it is then to be gently insinuated, by a rotatory motion, until it attains the fundus of the uterus. Much force ought not to be employed—and little or no pain is said to attend the operation. That dysmenorrhœa—as the writer has said elsewhere (*Practice of Medicine*, 2d edit. ii. 395: Philad. 1844)—may be induced by this cause, can scarcely be denied; yet it is, doubtless, rare, inasmuch as such a condition of the organ would prevent the flow of the menses altogether: and yet, in many cases of dysmenorrhœa the discharge is more copious than usual. It has been properly suggested by Dr. Ferguson (*loc. cit.*), that the employment of a bougie may operate beneficially by inducing a new action in the parts with which it came in contact, and that this may be the salutary agency—not the mere mechanical dilatation.]

C. LOCOCK.

DYSPEPSIA. (See INDIGESTION.)

DYSPHAGIA, derived from *δύς*, *difficultly*, and *φάγω*, *to swallow*. This term is applied to express a difficulty or impossibility of swallowing. When the extent and compound nature of the apparatus for deglutition is considered, it becomes obvious that this is a symptom which may arise from many and essentially different causes. Thus, all affections of the mouth, tongue, and pharynx, all lesions of nutrition, circulation, or innervation of the œsophagus, the pressure of tumours on this tube, &c. will give rise to this distressing and often fatal symptom.

In the common acceptation of the word, however, it is used to express affections of the œsophagus itself, either the result of some morbid condition of the part, or of pressure from neighbouring tumours. To these we shall principally direct our attention in this article; first enumerating the principal causes of dysphagia that have hitherto been described. These are

1. Congenital malformations of the mouth, tongue, soft palate, pharynx, and œsophagus.
2. Disease of the mouth, tongue, and pharynx.
3. Disease of the œsophagus.
4. External and internal tumours pressing on the œsophagus.
5. Disease of the cardiac orifice.
6. Affections of the larynx and epiglottis.

The congenital malformations of the mouth, pharynx, and œsophagus, which would act in producing dysphagia, are principally the extreme smallness of the tongue, the *microglossia* of Andral, a state, according to this author, owing to an arrest of development, and the consequent existence of the *hyoid* portion only of the tongue. Under these circumstances deglutition becomes extremely difficult, and several individuals so affected have been obliged to introduce the fingers in order to assist the process by pushing the food into the pharynx. We are not aware of any case of the opposite state (*macroglossia*) being known to produce dysphagia.

Adhesions of the tongue, either to the lower lip, or to the inferior part of the mouth, have been sometimes observed; indeed Andral considers that state called tongue-tied, to be merely a lesser degree of this malformation.

The last congenital malformation connected with the mouth is the absence of its anterior orifice; this is also to be looked on as an arrest of development; for it is the normal state of the mouth in the early periods of fetal life.

The pharynx is occasionally irregularly developed, terminating in a cul-de-sac, and presenting partial dilatations and herniæ of the internal membrane through the muscular fibres. The examples of absence of the part, or its duplication, have only occurred in monsters.

The malformations of the œsophagus are stated to be somewhat more numerous than those of the pharynx. Thus, in some cases, the upper portion terminates by a cul-de-sac, between which and the stomach there is nothing but cellular membrane. In other cases this is reversed, the tube proceeding upwards from the cardiac orifice for a few inches, and there terminating. In a few instances the œsophagus has been found reduced to a mere cord, while in others the obliteration did not take place till within a short distance from the cardiac orifice. (*Andral*.) Other malformations are described, such as its division into two canals; (*Blaes, Obs. Med. rarior*; see also *Billard and Michel*;) its obliteration above and persistence below forming a communication with the trachea, (*Martin, Observateur des Sciences Médicales*, 1825.)

In cases of congenital obliteration of the œsophagus, the symptoms, as observed in new-born children, are sudden vomiting when any fluid is attempted to be swallowed; this vomiting occurring without effort, and the ingesta being thrown up unaltered. In a case of absence of the œsophagus, (*Journal Comp. Dict. des Sciences Med.*) the drink was ejected through the nose; and it would appear that in some cases, as in stricture, a tumour may be observed in the neck previous to vomiting. The children of course die of inanition. In the case published by Sir Astley Cooper, the infant lived for eight days; in that recorded by Van

Cough three days; and in the example of obliteration first alluded to, the child lived eight days, during which time the stools and urine continued. It is scarcely necessary to remark, that in these melancholy cases we can do nothing but appease the cravings of hunger by nutritive injections and baths.

This is not the place to describe the various affections of the mouth and pharynx, attended with dysphagia, although they constitute the most common causes of dysphagia. For information on these subjects, the reader is referred to the several articles in which the individual diseases of the MOUTH, PHARYNX, &c. are particularly spoken of.

The sources of dysphagia arising from a morbid condition of the œsophagus are, its *acute or chronic inflammation*, the *growth of fungous or cancerous tumours* from its interior, *spasm*, and *paralysis*.

Acute inflammation of the œsophagus does not seem to be a common disease in the adult, the tube at this period of life being but little excitable; but in the infant, according to Billard, (*Traité des Maladies des Enfants*), it is more frequently met with, which perhaps is owing to the state of congestion in which the mucous membranes are often found after birth. In fact, œsophagitis may be an intra-uterine disease, as is proved by the occurrence of follicular ulceration in the part, in still-born children. The prominent symptom of this disease in the new-born child is an immediate vomiting when an attempt is made to swallow fluids: this vomiting is constant, often without any apparent effort; the milk is thrown up unchanged, and in several cases the usual symptoms of gastric inflammation have not been observed. A remarkable case of this disease is recorded by Dr. Abercrombie, in his work on the Pathology of the Digestive System. The symptoms were fever and difficulty of swallowing; the attempt to swallow sometimes excited cough, and frequently vomiting, with ejection of a soft membranous substance. This disease we have never seen but in one case, where the patient died of acute phthisis, and where there was difficulty of swallowing and vomiting. Here, however, the pharynx was affected.

Much has been written on stricture of the œsophagus, but the true pathology of the disease has not as yet been sufficiently recognized. There can be little doubt that in the great majority of cases it is the result of a chronic inflammation of the whole or part of the tube, producing an hypertrophy of its different tunics, but principally of the sub-mucous cellular tissue. The most perfect analogy exists between it and the disease called scirrhus of the pylorus and cardia, which is now admitted by the best pathologists to be the result of a chronic inflammatory process. The exciting causes, and the history of the various cases of stricture of the œsophagus, tend strongly to establish this opinion. Admitting this to be the case, we may hope to relieve the disease in its early period, and at all events we have a key to its physiological treatment even in its advanced stages.

The thickening is sometimes general, but more commonly partial, and varies from that which

would slightly narrow the tube, to its complete obliteration. It is almost always progressive, but Dr. Good mentions a case where the morbid process appeared to have been arrested, after having produced such a narrowing of the tube, as to prevent voluntary deglutition: this state continued for twenty years, during which the patient was supported by means of food introduced by a silver canula into the stomach. But this is a very rare case; almost every patient afflicted with this disease must die a slow and painful death. In some instances ulcerations have been met with above or below the stricture, (*Baillie*;) and in a few the semi-cartilaginous cellular tissue has become bony, as we see in other cases of chronic irritation of this structure. A dilatation often occurs immediately above the obstruction, which is sometimes visible when the patient attempts to swallow (*Odier*, Edin. Med. Comment. iii.)

Vegetations and other morbid growths have been met with in the œsophagus, where they produce a great and commonly fatal obstruction. A remarkable case of this kind is detailed by Dr. Monro, in which, whenever the patient retched, a large fleshy excrescence was thrown up into the mouth, reaching to the teeth. On dissection this was found to be a polypus, extending nearly through the whole course of the œsophagus.

We have before stated that dysphagia arising from a morbid condition of the œsophagus may generally be referred to chronic inflammation, spasm, or paralysis; let us, before speaking of the treatment of stricture, contrast the symptoms of these different affections.

**1. Chronic Inflammation or Organic Stricture.**—Invasion slow, the obstruction at first slight, but gradually increasing. Attempts to swallow often exciting great pain along the course of the tube to the base of the skull. Fluids more easily swallowed than solids in the advanced stages. Salivation, cough, hectic, and ejection of purulent matter—duration of the disease considerable. Exciting causes—irritations of mucous membranes.

**2. Active Neurosis, or Spasmodic Stricture.**—Invasion sudden, accompanied with a sense of constriction in the throat, and pain, even when the patient does not attempt to swallow. Disappearance often sudden—occasional relaxation by the use of the probang; relief from antispasmodic medicines; absence of hectic and signs of ulceration; exciting cause often mental emotion; occurring in nervous, irritable, hysteric, and melancholy persons.

**3. Passive Neurosis, or Paralysis of the Œsophagus,** may arise from disease of the cerebro-spinal axis, or occur independently of it. Sudden loss of the power of swallowing *without the symptoms of spasm*. No obstruction found by the probang. Cure by electricity.

Before speaking of the treatment of these species of dysphagia, we must remark that the spasmodic stricture may, from its violence or frequent occurrence, cause organic disease of the tube, by the injury done to the circulation and innervation of the part. In this way a spasmodic may pass into an organic affection, as ileus may pass into enteritis. This fact must always be borne in mind in the treatment of a case of spasmodic dysphagia.

The treatment of organic stricture has been

hitherto nearly empirical. In its early stage, when any chance exists of effecting a cure, time is often lost by the exhibition of useless nostrums; and great injury done by using bougies, when the part is in a state of acute irritation. In such a case, every thing that can irritate or excite the part should be most carefully avoided; the lancet should be used, and leeches boldly and repeatedly applied to the neck. These means should be followed by counter-irritation; and it is possible also that the use of mercury might assist in the removal of the disease. Indeed, we have a decided example of its efficacy in a case related by Dr. Munkley, (*Medical Transactions*, vol. i.) where in a very unpromising case, a perfect cure was effected by the use of this medicine. (See also *Rush*, *Inquiries and Observations*: *Dobson*, *Medical Observations and Inquiries*, vol. vi.)

In the advanced cases, advantage has occasionally been obtained from the use of the bougie, and the exhibition of hemlock. In such cases a seton would probably be useful, and the diet of the patient must be spare and unirritating.

The treatment of the second species must be that of spasmodic affections generally. It is often connected with deranged bowels, in which cases the judicious use of purgatives, followed by nervous and tonic remedies, will be advantageous. During the spasm antispasmodics may be given. A patient thus affected should avoid all debilitating causes, the use of very hot or cold drinks, and sudden changes of temperature. Constant exercise in the open air seems to be the best preventive.

It is obvious that the treatment of the passive neurosis, or paralysis of the tube, will depend on the presence or absence of organic disease in the brain or spinal marrow. If such should not be present, the best remedy appears to be electricity, of the good effects of which several examples are recorded in Dr. Monro's learned work. In one case the patient could only swallow when seated on the electric stool. This affection seems generally to be curable.

The pressure of tumours exterior to the œsophagus is not an unfrequent cause of dysphagia. They may be enumerated as follows: 1. Aneurisms of the aorta. 2. Enlargement of the bronchial glands. 3. Encephaloid tumours growing from the posterior mediastinum. 4. Enlargement of the cervical vertebræ. 5. Abscess in the neck. And, 6. Bronchocele. The diagnosis of most of these affections is difficult. In the case of aneurism of the aorta, the disease has more than once been mistaken for stricture of the œsophagus; and in one instance the tumour was ruptured by the incautious use of the probang. (*Abercrombie*.) A very remarkable case of encephaloid tumour, producing dysphagia and symptoms of phthisis, is detailed in the *Dub. Hos. Reports*, vol. v., in the report of the Meath Hospital.

The last cause of dysphagia which we shall notice, is the existence of disease in the larynx and epiglottis. On this subject much useful information may be obtained from the work of Louis, (*Recherches sur la Phthisie*.) It is obvious that any state of the larynx which causes pain or difficulty in its movements during deglutition, must be a cause of dysphagia, and there are cases where this is the prominent symptom. Destruction of

the epiglottis, or its tumefaction from œdema, will give rise to the same symptom from different causes. Of the last source of dysphagia, two most interesting examples have occurred lately to ourselves. In both patients there was great œdema of the neck, and in the cellular membrane in the neighbourhood of the parotids, and the epiglottis was so swollen as to form a large tumour preventing deglutition. In such cases the drink is discharged through the nose. Free puncturing with a lancet might prove serviceable in this affection.

WILLIAM STOKES.

**DYSPNŒA.** Difficult or disordered breathing. This term, which is generally applied to those derangements of the respiratory function which interfere in a *sensible* manner with its performance, would not be inapplicable to all instances of defect in this important process. Although in many instances only a symptom, dyspnœa is one of such importance, that it often becomes a principal object of treatment, as it constitutes the chief danger of the disease. For this reason it is important to examine more closely into its nature, and to distinguish between its several causes.

The muscular act of inspiration is excited by a sensation arising from the presence of black blood in the lungs. This act, in the natural state of the function, removes the sensation by supplying air, which converts the venous into arterial blood. But a variety of causes, presently to be considered, may impede or interrupt this conversion, and then the sensation becomes more or less perceptible and painful, and excites exertions of the respiratory forces, increased in extent and frequency, to relieve it. These may prove so far effectual as to supply the defect and remove the sensation of oppression; then there is hurried breathing rather than actual dyspnœa; but when, as is frequently the case, these supplementary exertions are insufficient to effect the due arterialization of the blood, it accumulates in the branches of the pulmonary artery and veins, and occasions the most oppressive and distressing sensations. A person suffering from them complains of an oppression on his chest, and cannot bear even the weight of the bed-clothes: he feels the room too small, and begs to have the windows opened; he is restless, and endeavours to find relief by sitting up; however great his courage, he is depressed and becomes alarmed by a feeling of impending suffocation. The semi-erect posture, by permitting a more extensive dilatation of the chest, often gives some relief; and to this degree of dyspnœa, obliging the patient to sit up, the term *orthopnœa* has been applied.

As the elements or principal parts concerned in the function of respiration are three, namely, the blood, the respiratory machine, and the air, the causes of dyspnœa may arise from changes in any of these. As the peculiar condition of the blood which is called venous is the immediate cause of the sensation of dyspnœa, so the blood being (if we may use the expression) *more venous* than usual, may give rise to the feeling of dyspnœa, without any derangement of the respiratory apparatus. Of this nature is the dyspnœa arising from violent exercise, which ceases as soon as the

flow of venous blood to the lungs becomes moderated by rest. Whether other processes, such as increased secretions, the digestion of blood, &c. be capable of producing the like effect, that is, of so changing the blood, that although the respiration be healthy, this fluid is not arterialized with sufficient rapidity to prevent the feeling of dyspnoea, is uncertain; but the stethoscope teaches us that the function of respiration is more active in some individuals than in others, and that there is also a difference in the same individual at different times. Laennec ascribed certain cases of habitual dyspnoea, in which the sound of respiration was even more distinct than usual, to an increased necessity of breathing, (*besoin de respirer*;) and although we should scarcely admit his instances (chronic bronchitis) to be cases in point, we think such a cause of dyspnoea to be in accordance with the pathological view which we have given. It seldom happens that persons with lungs in healthy action can exhibit such a state, the relative power of the organs being greater than the supposed increased demand: but those whose lungs are defective in consequence of disease, although not usually suffering from the defect, do certainly experience dyspnoea after taking food, and at other times, in a manner that will well admit of this explanation. It is through the blood, rather than in any other way, that diseases of the heart sometimes give rise to dyspnoea; any impediment to the pulmonary circulation causing an imperfection in the oxygenating process.

The following are the derangements of the respiratory function that may occasion dyspnoea:—  
1. derangements that interfere with the respiratory movements; 2. derangements that obstruct the passage of air to and from the pulmonary cells; 3. derangements in the pulmonary tissue that obstruct the action of the air on the blood.

1. The first of these, namely, those that interfere with the respiratory movements, are of two kinds; *a.* derangements of the mechanism of respiration, including spasm, paralysis, weakness or pain of the intercostal muscles, diaphragm, and other muscles concerned in respiration; rigidity or ossification of the cartilages or ligaments of the ribs, pain or rigidity of the pleura, and distortions of the spine or ribs: *b.* derangements external to the respiratory machine, but interfering with its movements, as pregnancy, abdominal tumours, and acute pain of the peritoneal coverings. Of these causes, spasm and paralysis of the respiratory muscles are the most important. In tetanus, and in paralysis resulting from severe injuries of the brain and spinal marrow, or from narcotic poisons, the dyspnoea thus produced is generally the immediate cause of death. In typhus fevers and other complaints of the extreme adynamic kind, dyspnoea arises from absolute weakness of the respiratory muscles; and hence the utility of stimulants. In other instances of fever, in which the brain is severely affected, the breathing is often hurried—in such cases the affection of the respiration depends on the condition of the brain and nervous system. Acute pain, whether in the thorax or abdomen, frequently produces an apparent dyspnoea, by rendering the full exercise of the organs of respiration intolerable. This especially occurs in pleurodynia, and in some cases of pleu-

ritis and diaphragmitis. Ossification, rigidity, or distortion of the thoracic parietes, and the pressure of abdominal tumours, do not often occur to a degree sufficient in themselves to produce dyspnoea; but by curtailing the sphere of the function, their presence may convert any trivial attack on it, by bronchitis or other cause, into one of a serious nature.

2. The second division of this class of causes of dyspnoea, those that obstruct the passage of air to and from the pulmonary cells, may properly be divided into, *a.* obstructions of the air-tubes, and, *b.* compression of the lung. Obstructions of the air-tubes may proceed from the state of the lining of the tubes themselves, from matters effused in them, or from tumours pressing upon them. Tumefaction of the mucous membrane of the trachea and bronchi, whether proceeding from inflammation, congestion, or œdema, and spasmodic constriction of the muscular fibres of the glottis and bronchi, are the derangements of the tubes themselves which not unfrequently occasion dyspnoea. Effusions in the air-tubes are the causes of dyspnoea in many diseases; and they may be either a redundancy of the ordinary secretion of mucus, as in slight inflammation, or of a new character, as coagulable lymph in plastic inflammation; pus, serum, and puita in the various degrees of bronchitis and catarrh; blood in bronchial hemorrhage and pulmonary apoplexy; tubercular and other matters from phthisical excavations, &c. Compression of the lung, by effusion into the sacs of the pleuræ and pericardium, whether of air, as in pneumothorax; or of liquid, as in pleurisy, hydrothorax, and dropsy of the pericardium; and by tumours in the thorax; is the other cause of dyspnoea which operates by obstructing the passage of air to and from the pulmonary cells.

3. The last class of derangements of the respiratory function that become causes of dyspnoea, are diseases in the pulmonary tissue itself, obstructing the due action of the air on the blood. Such are, *a.* the obliteration and filling up of the cells by effusion, of lymph, serum, and pus in peripneumony; of blood in pulmonary apoplexy; of serum in pulmonary œdema; and of tubercular matter in phthisis: *b.* an alteration in the condition of the membranes forming and lining these cells or vesicles; such as, the thickening and increased rigidity of the tunics of enlarged cells in pulmonary emphysema; and we conceive that an altered state of the lining mucus, the natural function of which when healthy is to facilitate the transfer of oxygen to the blood, is another cause which may give rise to dyspnoea. We have before noticed an excessive *quantity* of this mucus as a cause of obstruction to the passage of the air to and from the air-tubes, but we here suppose such a change in its *chemical quality* as would deprive the function of its aid. The bronchial secretion has been proved by late experiments to be much under the influence of the nervous system, and those cases of what is called nervous dyspnoea, in which signs of bronchial spasm are absent, and the sound of respiration distinct and even puerile, are probably referable to the last-named cause.

Besides in the blood, and in the organs of res-

piration, dyspnœa may sometimes have its cause in the third element of the respiratory process, the air. A deficiency of oxygen is, perhaps, the only state of the air that can *directly* occasion the feeling of dyspnœa; for carbonic acid, carburated hydrogen, and other noxious gases, when in considerable quantity, do so rather by exciting spasm or some other derangement of the respiratory apparatus. The stertorous breathing of those who have been exposed to the fumes of burning charcoal is also an indirect effect, and proceeds from the poisonous agency of the evolved gases on the nervous system. Although a defective proportion of oxygen in the air may contribute to the oppression which some persons of low respiratory powers experience in crowded rooms, other causes, such as heat, noxious animal effluvia, &c., have at least an equal share in exciting it. The dyspnœa felt at great altitudes, where the atmosphere is exceedingly rare, may with more fairness be attributed to the cause in question.

When a case of dyspnœa presents itself, it must be of great importance to discover from which of these several causes it arises; which we can never do with certainty without an examination of the physical signs. These will supply the desired information by positive indications in the case of organic disease within the chest, whether effecting the bronchi or the pulmonary tissue; and in the other cases enumerated, auscultation will give such negative signs, as will in the greater number of instances, in conjunction with the general symptoms, lead to an estimation of the true nature of the cause. For the characteristic signs of the diseases mentioned as causes of dyspnœa, we refer to their several articles respectively.

We have cited, however, one instance of the production of dyspnœa, in which, if it be not idiopathic, the symptom is not referable to any distinct disease. We allude to the case of *increased want of breath*,—"besoin de respirer," as Laennec has termed it,—and which we have referred to the venous condition of the blood increased beyond its natural standard. Such a dyspnœa can be detected only by the absence of the signs of every other cause: where, therefore, a dyspnœa occurs, whilst pure air is found to penetrate freely into every part of the lungs, and the diseases which modify the state of the bronchial membrane and its secretion have not existed, the disorder must be necessarily referred to an unusually venous or *carbonized* state of the blood. If we attempt to rise one link higher in the chain of causes, we shall find that physiology reveals to us only one probable mode in which this state is itself produced; and that is, by an excessive formation of those secretions which are, in relation to the blood, defective in carbon. Such is urea, a predominant principle in the urine. From its formation, principally, the carbonic acid exhaled from the lungs is supplied, and if we assume the possibility of deviation from the healthy proportion of this supply, we enter on ground less sanctioned by experience than by analogy. We conclude this subject with the remark, that the medicines which Laennec commended as capable of diminishing the "besoin de respirer," (belladonna, stramonium, conium, &c.,) if they act as

narcotics, deadening the *sensation* of dyspnœa, would not be eligible; but if they act, as is not improbable, by diminishing the secretions which render the blood venous, then they really would relieve the function, and not merely stifle the symptom.

C. J. B. WILLIAMS.

**DYSURIA** (from *dûs*, *ægre*, and *ούρον*, *urina*.) Dysuria, or difficulty in voiding the urine, is a symptom of many different diseases, and arises under a variety of circumstance. Although only a symptom, it well merits careful consideration, from the suffering which it occasions, and the serious consequences to which it often speedily leads.

Dysuria exists in every degree, from the slightest to the most intense, when the difficulty terminates in a total inability to expel the urine. The consideration of the subject in this extended sense will lead us to treat of retention of urine, which, though peculiarly the province of the surgeon, is an object of deep interest to the practical physician.

Dysury is often attended with smarting pain; sometimes the pain is lancinating or shooting, at other times it is accompanied by the most distressing efforts to expel the contents of the bladder, such as have been described in the article **CALCULUS**. Pain, however, is not a necessary accompaniment of dysury; thus, the imperfection with which men advancing in life discharge the last drops of urine, although wholly unattended with pain, is a true dysury, though in almost all those cases where the expulsion of the urine is prevented by a deficient power in the muscular coat of the bladder, there is no pain. In such instances, as the difficulty of discharging the contents of that organ increases, no urine escaping, or only a small quantity constantly dribbling away, the urine gradually accumulates and produces distension of the bladder. If the progress of the disease has been slow, and the patient is not of an inflammatory habit, the bladder sometimes acquires a size almost incredible. It expands in all directions, pressing downwards, backwards, and laterally, filling all the pelvis not occupied by fixed viscera, and forcing behind and above it those that are moveable. Under such circumstances the bladder has risen to the umbilicus, or even higher, pushing up the adjacent organs upon the diaphragm, and thus impeding respiration. Such enormous distension has occurred chiefly in females, in whom the bladder is much less irritable than in men; and the quantity of urine evacuated by the catheter in these cases has sometimes amounted to twelve quarts. Instances, indeed, are recorded where it is said to have been more than five times as great; but in all probability many of these extraordinary histories have originated in mistake or exaggeration. Frank relates a case in which forty quarts of urine were found in the bladder after death. (J. P. Frank, *De curand. hom. morb. Retentio urinæ*.) To allow of such expansion of the bladder, its coats must be healthy and pliant, which in many instances of urinary disease is far from being the case. When this organ is indurated and contracted, a comparatively small accumulation of urine may prove fatal.

The fluid descending through the ureters find-

ing a resistance to its entrance into the bladder, fills and dilates those tubes, and at length produces the same effect on the cavities of the kidneys. The pressure thus caused on them diminishes or wholly arrests their secretion, while the absorbent vessels carry a part of the urine into the circulating mass. The perspiration, which now becomes profuse, has a strongly urinous smell, and the taste of urine has even been perceived in the mouth. (Heberden, *Comment. de Morbis.*) Under such circumstances inflammation of the distended viscera speedily takes place; and if no relief be obtained, the urine escapes by a gangrenous aperture in the bladder or urethra, into the surrounding cellular substance, or into the peritoneal cavity. The extent to which the urine is diffused in the cellular membrane is often extraordinary, sometimes reaching as high as the soft parts covering the chest. When the urethra has given way behind a stricture, the scrotum is usually swollen enormously by the acrid fluid, which strikes with gangrene whatever it touches; at other times, the only *visible* indication of what has happened is a dark sphacelated ring surrounding the orifice of the urethra.

Retention of urine, when accompanied by inflammation, is always productive of great constitutional disturbance: the skin is hot; the pulse rapid; the thirst urgent; the tongue speedily covered by a dark crust, and great anxiety and restlessness prevail. Vomiting, hiccup, and extreme tenderness of the abdomen indicate the communication of disease to the peritoneum; low delirium comes on, and the patient dies comatose or convulsed.

We can in general depend on the report of the patient as to the existence of difficulty in expelling the urine; but it often requires a very careful examination, before we can ascertain the true state of the bladder. The urine may flow with pain, or dribble away insensibly, or the patient may feel not the slightest inclination to discharge it; yet under all these circumstances the bladder may become disturbed to such a degree that the most dangerous consequences result from neglecting to relieve it. Distension of the bladder can seldom be mistaken, if the finger be applied to its lower fundus through the rectum or vagina, while the other hand is laid upon the hypogastrium; in general a distinct undulation of the fluid may be produced by this method. All doubt, however, will be removed by calling in surgical aid, and having the catheter introduced. Some striking instances are recorded, where the bladder in a state of excessive distension has been mistaken for a collection of purulent matter, or for abdominal dropsy, or ovarian tumour; and proposals have been made for the evacuation of the fluid by tapping.

**Causes.**—The circumstances which interfere with a due performance of the excretion of the urine are very numerous. Dysuria may arise from the acrimony of the urine irritating the passages through which it is forced, and increasing their natural sensibility; thus, both alkaline urine and that which contains an excess of acid, have this effect. Difficulty in voiding the urine is also occasioned by an irritated or inflamed condition of the urinary organs, or of the adjacent and asso-

ciated parts; by which the healthy sympathy between the muscles which retain, and those which expel the urine, is disturbed or destroyed. Thus, dysuria exists in gonorrhœa; with inflamed prostate gland; with urinary calculus in any of the tubes or cavities, provided it occasion irritation; it also exists in cystitis; in inflamed ureter; in nephritis; and with inflamed hemorrhoids; inflammation of the rectum, and irritation of it from worms, or from the tnesmus of dysentery. The dysuria which accompanies this last disease is often productive of great distress, and has in our own experience sometimes occasioned retention, requiring the warm bath, and even the catheter. Dysuria also occurs in the painter's colic, from a sympathy between the bladder and the intestines in their state of spasmodic irritation. The irritations and inflamed conditions of the vagina and uterus produce dysuria: thus it is met with in the newly-married; in cases of gonorrhœa in females; in the early period of pregnancy, and as a warning symptom in approaching abortion. Dysuria is likewise a principal symptom of the warty excrescence which occasionally forms at the orifice of the female urethra. (*Clarke, Diseases of Females.*)

A frequent cause of dysuria, and of its more aggravated form, *strangury*, is the internal exhibition of cantharides, and their external application in the form of blisters and issues: we have also known vesication from scalding water produce the same symptom; but this sympathetic effect is of rare occurrence. Other substances, of a much milder nature than cantharides, are productive of irritation of the urinary organs when taken in excess: thus Rhenish wine and new beer have been known to occasion dysuria; and the latter is considered by continental writers as no unfrequent cause of puriform discharge from the urethra. Increased secretion of urine, as in diabetes, and from the operation of diuretics, is often attended with pain and difficulty in voiding it. In some individuals asparagus is productive of much urinary irritation; but we have never observed this effect from gooseberries, which are more powerfully diuretic than many drugs referred to this class in the *Materia Medica*.

Dysuria sometimes exists, as a mere nervous affection, in connection with hysteria; and sometimes it arises from neuralgia of the bladder. The influence of dentition, which is so often manifested in disorder of the digestive organs, is occasionally extended to the urinary apparatus. This affection is also produced by everything which mechanically obstructs the discharge of urine: thus, strictures of the urethra or prepuce; enlargement of the prostate gland; varicose veins at the neck of the bladder; polypous or fungous growths of its internal lining; intromission of the bladder, (*Aubin, Pathologia Externa, t. ii.*) the intestines falling into the cavity so produced; projecting folds of the mucous membrane—are all occasional causes of dysuria. It may also originate from calculi in any of the urinary passages, from the kidney downwards; from hydatids; coagula of blood; inspissated mucus; false membranes or laminæ of coagulated albumen plugging the ureter or urethra. Morgagni (*De Sedibus, &c. Epist. 41, sect. 13.*) and others have given accounts of such membranes, found in the bladder or urethra, or expelled

with the urine; but cases are also recorded which serve to support the idea that part of the internal surface of the bladder is sometimes thrown off and discharged by the urethra.\*

Through the kindness of Dr. Weir, a remarkable case of this nature fell under our observation some years ago. A female, who was delivered by the forceps, after the head of the child had been arrested for twelve hours, had, two days afterwards, an inflammatory attack with pain in the hypogastrium. Incontinence of urine followed; several small sloughs came away, and one was extracted from the meatus. About three weeks from delivery, retention of urine took place, and, after many hours, a large slough was forced off suddenly with a gush of urine, which continued to flow to the extent of two quarts. On carefully examining the slough, it was found to consist of a thin membrane without any perforation, six inches in length by four in breadth. One of its surfaces was granulated, rough with earthy particles, and stained with blood of a brown colour; the other presented the appearance of cellular membrane, with small flattened masses of what looked like adipose tissue. It was very extensible, and on minute inspection an appearance of muscular fibres could be traced within its substance. That the bladder had in this case suffered a very severe injury was obvious: for the urine, for some time before and for a considerable time after the discharge of the slough, was mixed with blood, and deposited much purulent mucus: there was also at one period a phosphatic deposit from the urine, and two minute spongy calculi were voided. No opening could be detected between the vagina and bladder; and after the slough had been discharged, six or seven ounces of urine were from time to time voided in a stream.

The obstruction producing dysuria is sometimes dependent on a change in the position of the bladder, as in hernia of that organ, and in prolapsus of the rectum or uterus.

Ruysch gives a very curious case of complete prolapsus of the uterus, accompanied by the most excruciating urinary sufferings, in which he cut into the front of the prolapsed tumour, and extracted several calculi with a successful result. (*Obscrb. Anat. Chirurg. Ob. 1.*)

On other occasions the cause of obstruction to the flow of the urine lies exterior to the bladder and urethra; as when it arises from ligatures round the penis, swelling of the prepuce, aneurism of the corpora cavernosa, abscesses in the vicinity, carcinomatous indurations, tumours within the pelvis, the gravid uterus, retroverted uterus, the menstrual fluid collected behind an imperforate hymen, feces or other hard substances lodged in the rectum.

Inability to void the urine sometimes arises from rupture of the bladder, which may either be complete, or involve only the mucous and muscular

tunics. The sudden occurrence of pain in the region of the bladder, and incapacity to expel the urine after the reception of an injury, the absence of tumour of the bladder when examined through the rectum or vagina, and the scanty discharge of jets of bloody urine by the catheter, will in general point out the real nature of the accident. It is to be observed in relation to the diagnosis, that although the bladder have been ruptured, there is often circumscribed tumour in the hypogastric region. In an instance of ruptured bladder which occurred in our practice some years ago, a urinary abscess which pointed in the hypogastrium was punctured on the twelfth day after the accident, and the patient survived till the twentieth. On inspection, the small intestines were found glued together, and to the abdominal peritoneum, by an albuminous exudation; and thus a partition was formed between the upper and lower portions of the abdominal cavity, which stretched across in an arched form a little below the navel. The lower cavity, which was of great extent, and communicated under the left Poupart's ligament with a sinus passing for several inches down the thigh, was more than half filled with putrid urine, pus, flakes of albumen, and liquid feces; for the intestines had given way in several places. The bladder was seen lying collapsed in its natural situation, and presented posteriorly, on the left side of its upper fundus, a rounded opening about two inches in diameter. The peritoneal coat was extensively separated at this point, and its edges hung loose in flocculent shreds. It is probable that in this case only the mucous and muscular tunics were at first ruptured, and its long duration afforded some slender hope of a favourable termination: the only chance of success was from an early puncture of the hypogastric tumour, which we proposed in the second day after the accident, but it was overruled in consultation.

Dysury often originates in a want of power in the muscles which expel the urine. The muscular fibres of the bladder, if long kept on the stretch, gradually lose more and more of their contractile force, and at length become wholly paralysed. Instances of this description are of daily occurrence, when individuals have been prevented from emptying the bladder by delicacy, or by the absorbing engagements of business or pleasure. The pressure of the child's head in the latter stages of parturition often keeps the urine pent up, and thus induces inability to expel it after the obstacle is removed. The same loss of power in the fibres of the bladder, though in a much more dangerous form, arises from affections of the brain and spinal cord, and from pressure and disorganization of the nerves which supply the bladder: in this way difficulty of voiding the urine occurs in fevers, in extravasations and effusions within the cranium, in pressure from fractures of the bones, and in injuries and chronic diseases of the spinal cord.

Among the causes of dysuria, there is none more familiar to common observation than the exposure of the body to cold. It acts by producing a contraction of the urethra, more especially in men, disturbs and destroys the natural consent of parts, and in the end induces a torpor of the bladder. Wherever a predisposition to dysury exists from mechanical obstruction or otherwise, the

\* *Rohaut, Mémoires Acad. Roy. des Sciences, 1714.* (The membrane had distinct blood-vessels—a male.) *Köch. Haller Disputat. Medic. t. iv.* (A female after abortion.) *Ruysch, Adversar. Anat. Dec. ii. n. 9.* (A female after parturition.) *Willis, De Urinis, cap. v.* (A female suffering under calculus.) *Fahner, Beiträge zur practischen und gerichtlichen arzney künde, b. i. u. v. Guisard, Pratique de Chirurgie.*

action of cold becomes an immediate exciting cause.

**Treatment.**—In attempting the treatment of cases of difficulty or inability of voiding the urine, our first object ought to be to ascertain the cause from which it proceeds, and, if possible, to remove that which has occasioned the symptom: if we succeed in accomplishing this, the dysuria in a great majority of cases will cease. In every instance of this affection it is of especial importance to discover how far it is connected with an inflammatory or plethoric condition of the body, or of the urinary organs in particular; and should it be so, to have speedy recourse to bloodletting and leeches. When dysuria occurs during pregnancy, or is symptomatic of approaching abortion, the adoption of this practice will generally be required.

When the affection is of a spasmodic character, or accompanied by pain or irritation, the warm-bath, warm applications of various kinds, and opiates by the mouth, friction, or enema, will be found of the greatest utility. The last of these remedies is particularly serviceable in that form of dysuria which is caused by the application of cantharides. In many cases of dysuria, even where it depends on a certain degree of mechanical obstruction, the operation of a smart purgative has produced immediate relief; and in every instance it is a safe rule to unload the bowels as speedily as possible, for by this means we relieve the neck of the bladder from pressure, and promote the healthy sympathy of the parts. In dysuria and retention of urine of a spasmodic character, the tincture of the muriate of iron, in small repeated doses, has proved a valuable remedy in the hands of the late Mr. Cline and many others. The sudden effusion of cold water on the genitals and neighbouring parts has sometimes procured a flow of urine when all other methods have failed, partly, perhaps, by causing a relaxation of spasm, but chiefly by rousing the contractile powers of the bladder. But when the vigour of this organ is actually impaired, we must have recourse to stimuli of far more effective and permanent operation. Blisters to the loins and sacrum, the formation of eschars by moxa or potassa, and the cautious exhibition of cantharides, are the remedies which will be found of most avail.

When dysuria appears to be connected with the scanty secretion or acrimonious quality of the urine, diluents are to be given freely, along with such mild diuretics as the spiritus atheris nitrici, spirit of juniper, decoction of the fibrous roots of the leek, liquor potassæ with hyoscyamus, bicarbonate of soda, or Seltzer water. Stronger diuretics are in severe cases given with advantage, such as the parsley breakstone (*alchemilla arvensis*), seeds of the wild carrot (*daucus sylvestris*), and the oil of turpentine. Dysuria from alkaline urine must be treated on the plan already laid down in the article CALCULUS.

Should inability to void the urine have arisen from long voluntary retention of it, the patient ought to immerse his feet in warm water, and, placing the penis in a basin of the same, make gentle pressure on the hypogastrium, and endeavour to evacuate the bladder, when he will often succeed without any farther assistance. The immersion of the penis in warm water rarely fails to

give great relief in the painful micturition which attends gonorrhœa. When difficulty of voiding the urine occurs, as it very often does, after parturition, the simple expedient of making pressure on the hypogastrium with a warm sponge will not unfrequently save the patient from the necessity of having the urine drawn off by the catheter. But to this instrument we must have recourse in very many cases of retention of urine; and it is fortunate that the surgeon possesses in it the means of removing a symptom which is at once most distressing and dangerous. The catheter, however, is not always successfully employed, even by surgeons of acknowledged eminence and dexterity; and it then becomes a question how the danger can best be averted. If the symptoms are not urgent, a little delay may still be allowed, to give a farther trial to the most important of the remedies already enumerated, and to the well-directed employment of sounds and catgut bougies; but we must on no account wait so long as to incur the slightest risk of gangrene or rupture of the bladder. The only means now remaining by which the life of the patient can be saved, is, to puncture the bladder, or open the urethra behind the obstruction, should such be the nature of the case. This, however, is in the province of the surgeon, and therefore foreign to the nature of our work.

W. CUMIN.

[EAR, DISEASES OF THE. (See OTALGIA and OTITIS.)]

**ECTHYMA**, (from *ἐκ*, *ex*, and *θῆναι*, *fervere*,) a disease of the skin, characterised by an eruption of phlyzacious pustules, neither contagious nor infectious.

**Synonymes.**—*Τέρινονθος* vel *θήρινονθος*,\* et *ἐπινυκ-  
ρις*,† (*Græcorum*;) *therebinthus*, (*Latinorum*;) *albotin* vel *albotēs*,‡ *schera* et *botisor*,§ (*Araborum*;) *terminthus*, (*Wiseman*, *Turner*, *Lorry*, *Plenck*;) *epineytis*, (*Sauvages*;) *psoride crustacée*, (*Alibert*;) *Erbseublattern*, (*Teutonicæ* sec *Plenck*;) *eiternde Flechte*, (*sec. Sprengel*;) *pa-  
pulous scall*; *ulcerated tetter*.

By the term with which Willan chose to design

\* "Some will have the denomination from the likeness of the pustule to the fruit of the *terebinthus*. Others, with more reason, read it *ἐπὶ νύκτι*, *ciccr*, which it somewhat resembles." *Turner*. *Vide Hipp. Epidem. lib. ii. sect. 11*; *De Humor. xi. 1*; *Galen. in Exeg. dict. Hipp. item Comment. 3*, *De Humor. et Comment. 4*, in *lib. vi. Epidem.*; *Ægin. l. iv. c. 4*; *Ætii. lib. ii. tetrab. iv. c. 63*; *Fœs. Eccl. p. 615, 616*; *M. Aurel. Sev. l. de Epinyctid. part. ii. contr. 3*; *Dioscorides Alexand. vide Gorrei defin. Med.*; *Oribas. lib. vii. Synop. cxxxvi.*

† From *ἐπὶ* and *νύξ*, so called, according to some, because the eruption first appeared, or only appeared, by night, and, according to others, because it was most troublesome at night. But whatever be the reason of the etymology, it is plain, from the description of this eruption left us by the best authorities, that it consisted of phlyzacious pustules. *Vide Hipp. Protriet 2*, *De Intern. Affect.*; *Celsus, lib. v. c. 28, sect. 15*; *Paul. Ægin. lib. iv. cap. 9*; *Oribas. Synops. lib. vii. c. 37*. The Arabians translated the term by *sera* or *schera*, and sometimes *botisor*, (*Avicenn. lib. iv. fen. vii. tom. iii. c. 1*) which last being of the same etymology, restored it to its natural connection with *terminthus*. *Actuarius*, as it appears to us with little show of reason, insists on a distinction between *epineytis* and *terminthus*, (*Meth. Med. lib. ii. c. 11, 12*.) Some authors, bearing entirely upon the derivation of *epineytis*, have been led into the mistake of considering it the same as the *urticaria tuberosa*—an error which *Sennertus* very properly corrects.

‡ Fallopp. l. de Morb. Gall. c. 5, tom. i. p. 686

§ Avicenn. lib. iv. fen. 3. t. i. l. 1. and f. 7. l. iii. c. 1, *Hensler de Herpete*, p. 30; *Roussel de Herpete*, § 99.

nate this disease he lost hold of the thread which led us to the knowledge which the ancients had concerning it. In the synonymy we have endeavoured to recover it, thus to connect ancient experience with modern observation, the only substantial use of learning.

The eruption in this disease consists of large round pustules generally distinct and sparingly scattered, each having a hard, red, elevated base, terminating in a thick, hard, greenish or dark-coloured scab, which, falling off, leaves generally a livid red spot of longer or shorter duration, sometimes a superficial cicatrix, more rarely an ulcer, seldom a tubercle.

This eruption is frequently confined to the extremities, appearing most commonly on the legs, on the outer side of the thighs, arms, and forearm, frequently on the abdomen, nates, lumbar region, neck, and front part of the chest, rarely on the face or scalp, and very seldom occupies the whole body.

The pustules sometimes break out together in successive crops; but generally they appear, go through their progress, and terminate, independently of each other, some being on the decline whilst others are appearing.

This eruption is sometimes, but not generally, accompanied with fever; it is more frequently attended with restlessness, a state of general irritation or crethism, and sleepless nights. Morbid phenomena produced by gastric and intestinal irritation, as anorexia, &c., almost always appear during the course of the eruption. Sometimes fever, anxiety, great general distress, and pains of the limbs precede the eruption, which subside on its appearance. If the pustules be abundant, thickly set, violently inflamed, and acquire a great size, considerable symptomatic febrile action may be present; and if they ulcerate, are slow in their progress, and of long continuance, emaciation, debility, and regular paroxysms of hectic fever supervene.

Each pustule generally commences in a circumscribed red inflamed point, which becomes gradually raised, and in the course of a few days acquires a size varying from that of a lentil to that of a sixpence; their apex is soon observed to point with pus, whilst the base continues hard, circumscribed, and of a bright red colour; at the end of three or four days the pus dries, and scabs, more or less thick, are formed, which, when they fall, leave spots of a dark red colour. The pustules vary in size, from that of a small pea to that of a sixpence or larger. They are generally distinct, but sometimes they form irregular clusters. Their development is frequently accompanied with very acute stinging pains, similar to what precedes *erysipelas*, or the *herpes zoster*.

From this their usual course considerable deviation is sometimes observed. Their progress is sometimes tediously slow and imperfect. Suppuration in some cases is established rapidly, and in others it is only effectual after many days; sometimes the pus is in very small quantity, occupying only the apex of the pustule, the base remaining broad, hard, and inflamed; sometimes, more especially on the hands and feet, the pus raises the cuticle over all the extent of the pustule, giving it the appearance of a bleb or *bullæ*. Some of the

pustules are occasionally resolved, thin, white scabs forming successively over their surface; sometimes ulcerations, more or less deep, succeed the pustules, especially those seated on the lower extremities, or such as follow scarlatina or small-pox, and sometimes slight indurations succeed to the scabs. The pustules are not always distinct, but sometimes as it were confluent, and though generally accompanied with a burning, itching or stinging pain, they are also sometimes entirely free from any painful sensation.

It has been doubted whether the term pustule was properly applied to the eruption of ecthyma which supposes an active inflammation and suppurative action to constitute the essence of the disease,—a supposition inconsistent with the state of system existing in all cases as the predisponent cause of this disease; and it has been asserted that a minute examination does actually disclose a state of vessels differing materially from such an action; that, instead, a lesion of some minute vessel takes place in each spot of ecthyma, and a kind of petechiæ are thus produced. But from some cause, depending either on a minor degree of debility of the system to that in which the petechiæ remain quiescent, or on a greater degree of irritability of the skin, attempts are made to repair the mischief by the vessels of the part, and inflammatory action takes place. The minute vessel thus ruptured has its extravasated contents mixed with the coagulable lymph poured out by the vessels labouring to repair the mischief, and the mixed fluids, drying on the spot, form the minuter scabs. But the constitution being unequal to carrying through the process in a healthy manner, irregular attempts at suppuration take place, and the bulk of the scab is usually surrounded by and partly mixed with a minute portion of ill-formed pus, which, drying, increases the bulk of the scab. Many of the minute vessels concerned in this process being too relaxed, their secretion is mixed with and deeply coloured by red globules, which escape under the increased action. The scab now becomes a cause of irritation to the surface on which its basis rests; the bloody purulent secretion increases, becomes inspissated, and attached to the mass; ulceration gradually destroys the surrounding cutis, and the margin of sound skin becomes elevated and thickened. The scab, by the continuance of this process, is gradually elevated and rapidly enlarges, a fresher and broader ring of growth being added to its basis every three or four days. (*Plumbe*, on Diseases of the Skin.)

This ingenious account of the process of the eruption of ecthyma is not in strict accordance with the phenomena, but, on the contrary, is in many respects at variance with them: it rests in its chief points upon suppositions purely gratuitous, for it has yet to be ascertained, and we are inclined to deny it, that even petechiæ are nothing more than ruptures of minute vessels; and it is directly contradicted by other observers who have examined attentively the structure of the pustules of ecthyma at the different stages of their progress. According to them, in their *first* state of red elevations, there exists only a vascular injection with a round circumscribed tumefaction of the skin; that, in their *second* state, a certain quantity of

purulent serosity is deposited, under the epidermis, at their summit, more rarely over all their surface; that, in their *third* state, a substance of the nature of a false membrane is deposited in the centre of the elevation, which is evidently perforated; that, in the *fourth* state, after this substance has been extracted and the epidermis removed, the pustule appears in the form of a little cup surrounded with a hard broad border; and that, in their last and *fifth* state, the border, during the following days, gradually disappears, whilst a small cicatrix is formed under the scab, the centre of which is sunk into the point where the perforation has been observed.\*

The phlyzacious pustules of ecthyma may be developed in the healthiest body by the local application of certain irritating substances. Thus tartar emetic, in powder or in ointment, after the manner of Autenrieth, is capable of giving rise to them; and the same has been observed of certain pulverulent matters, as metallic powders, sugar, and lime, which accounts for its being frequently seen in masons and grocers. But it is more commonly met with as a symptom and effect of a general disordered state of body, or a sympathetic consequence of irritation or inflammation of some internal organ. Hence it has been observed to supervene upon unusual fatigue, long-continued exertion, much night-watching, great mental anxiety, and strong moral affections; and it has been most frequently observed in persons who have injured their constitutions by previous excesses, by the abuse of spirituous liquors; or who have suffered in consequence of deficient nourishment, or unwholesome food, or surfeits; whose health has been impaired by dwelling in dark, damp, cold, and close habitations; or by habits of sloth and uncleanness; or whose constitutions have been debilitated by the effects of malignant fevers, as small-pox, measles, and scarlatina. Hence it is favoured by a moist and cold atmosphere, though it occurs most frequently in spring and summer, and is met with frequently in infants, in the decline of life, and in women, more especially during pregnancy, or whilst suckling, or coexisting with amenorrhœa; and is frequent in large cities, hospitals, prisons, garrisons, work-shops, and manufactories. For the same reason it is so often accompanied with symptoms of gastric and intestinal disorders, with loss of appetite, pain in the epigastrium, irregularity of the bowels, lassitude, headach, &c.; and has been observed frequently coexisting with chronic inflammation of the mucous membrane of the stomach and intestines, with such concomitant symptoms as inflammation of the conjunctiva, and of the mucous membrane of the pharynx; and has sometimes been observed to be critical in acute *gastro-enteritis*. In predisposed habits, trifling local irritation will produce it, as leech-bites, and even the friction of the clothes; so that some authors have remarked the pustules to be frequently seated under the wristbands and collar of the shirt, the waistband of the breeches, and at the gartering place above the knee.

Though the eruption of ecthyma preserves its

character with comparative constancy, and is one of those cutaneous affections the least convertible and disposed to pass into others, it sometimes develops itself in the exacerbations of other inflammations of the skin, as in *lichen*, *prurigo*, *scabies*, and *variola*, but shows, in general, a closer connection with *furunculi*.

Though such is the general appearance, course, and causes of this disease, they admit, as we have noticed, of considerable diversity, sufficient, in a practical point of view, to justify a division of the genus into several species; and though we prefer the specification of Willan and Bateman to that of Alibert, (*psoris crustacea acuta* and *psoris crustacea chronica*), as being more true, precise, and practical, we shall venture upon a slight alteration of the name of one species, so as to make them all more distinct and consistent; and shall add to the genus the syphilitic form of the disease. The following will therefore be our arrangement.

1. Ecthyma *vulgare*.
2. Ecthyma *infantile*.
3. Ecthyma *luridum*.
4. Ecthyma *febrile*.
5. Ecthyma *syphiliticum*.

1. **Ecthyma vulgare.**—*Syn.* Epinyctis vulgaris (*Saurages*); Psoris crustacea acuta (*Alibert*); Ecthyma aigu (*Rayer*); die gewöhnliche eiternde flechte (*Teutonice*).

In this species of ecthyma, generally after some days of languor and general oppression, of loss of strength and appetite, of derangement of the digestive functions, of headach, of pains in the bowels or of the limbs, and after less refreshing nights, with, more rarely, redness and inflammation of the conjunctiva, and sore throat from erysipelatous inflammation of the pharynx, an eruption, accompanied with sharp stinging pains, appears on some part of the extremities, or on the neck, shoulders, or breast. This eruption, which is usually completed in three or four days, consists of small red circumscribed elevations of the skin, not yielding or disappearing on pressure; for three or four days they continue to enlarge, becoming surrounded with an inflamed areola, which is hard and circular, and in young subjects of a bright red colour; having suppurated at their apex, which is distinguished by a small dark point, after a day or two they break, discharging first pus and afterwards a thinner fluid, which quickly concretes into dark-brown or greenish scabs. The constitutional derangement which preceded the eruption is now abated; the inflamed areola extends itself, becoming gradually paler as it enlarges; in about a week, all the pain, soreness, and inflammation subside, and the scabs soon after fall off, leaving no mark behind. If they continue adherent to the skin for a longer time, which sometimes happens, they leave, when detached, a dark red spot, or, more seldom, a superficial cicatrix, in size resembling those of small-pox, but less deep. If the pustules be situated in the neighbourhood of lymphatic glands, these latter become sometimes swollen and inflamed.

The whole process of this eruption, in general, occupies from seven to fourteen days, and one eruption frequently completes the disease.

This species is most commonly met with in

\* Ecthyma, Dictionnaire de Médecine et Chirurgie Pratique.—Ch. Ed. Asselin Essai sur l'Ecthyma, Paris, 1827.

spring and summer; it affects principally young people and adults, and is occasionally observed in women during gestation. It frequently follows excessive fatigue, severe or prolonged exertion, night-watching, nurse-tending, anxiety, vexation, and other emotions of mind, errors of diet, and indulgence at table. It appears to be very much connected with the state of the digestive organs, but seems to depend upon something more than their mere derangement. It has been well expressed by Bateman, by a state of distress of the constitution. It is also sometimes observed as critical of acute gastro-enteritis.

In general, this species does not stand much in need of the interference of art. Gentle, cooling, and saline purgatives, as senna, manna, and tartrised soda or potass; acidulous diluent drinks, as whey; and light, cooling diet, afford ample means of cure. In robust, sanguine, or plethoric subjects, a small bloodletting accelerates the progress of the eruption, and renders these means more efficacious. If much irritation and restlessness be present, and much local uneasiness, the tepid bath is the surest means of affording relief. If the alvine evacuations are unhealthy, five grains of the pulv. hydrargyr. cum cretâ may be taken at bed-time, with a few grains of Dover's powder, but even this is seldom necessary. The diluted sulphuric acid, simple or aromatic, is a good tonic as the disease declines. If the local affection demands any treatment, an emollient poultice is the best.

**2. Ecthyma Infantile.**—*Syn.* Terminthi neonatorum—Schülblasen, *Teutonice* (Plenck.)

In infants of a constitution naturally weak, or disordered by bad or insufficient suckling, or by being brought up by hand upon food not suited to the powers of their digestion, an eruption of phlyzacious pustules is a common occurrence.

In this species, as the former, the eruption is partial, chiefly affecting one particular part of the body, and, as in the former also, several pustules may appear together; but more commonly the disease consists of a successive eruption of individual pustules, by which its duration is sometimes extended to several months. The pustules are first observed near the groins, on the abdomen near the umbilicus, near the axillæ, and on the thighs or nates; sometimes they are not confined to the trunk and extremities, but also occupy the face and scalp. The course and progress of each individual pustule is the same as that of the *ecthyma vulgare*, but they are in general more irregular in their size, a large being frequently observed by the side of a very small one; their form is circular, but they vary more in colour, being sometimes of a bright red, sometimes of an amaranthine, and sometimes of a livid colour, according to the strength or weakness of the infant. The pustules of this species are more disposed to suppurate extensively, and more apt to terminate in ulcerations, which in weakly infants heal imperfectly, being covered by a thin, filmy cicatrix, easily re-opening or abraded, marked by a peculiar puckering of the surrounding skin. In some severe cases, generally only to be found amongst the most indigent, gangrenous eschars and deep sloughing ulcers, similar to those of *erysipelas infantile*, are not uncommon terminations of the

pustules of this species. Occasionally, also, after threatening suppuration, the pustules gradually diminish and terminate by a succession of desquamations.

The process by which an improper nourishment develops this disease appears to consist not only in a deranged state of digestion and assimilation, but also in the production of inflammatory affections of the alimentary canal; for chronic inflammations of the digestive organs are frequently observed in connection with this eruption. But all the chronic derangements of the abdominal organs of infants are capable of inducing this eruption, and hence phlyzacious pustules are common symptoms of the marasmus which depends upon obstruction of the mesenteric glands. Cold and moisture appear frequently to furnish the exciting causes of this eruption. According to Plenck, it has sometimes prevailed epidemically.

The treatment of this species consists in changing the nurse or in altering her milk by diet or medicines, or in adapting the diet of the child to the powers of its digestion. For this last purpose, asses' milk, goats' milk, and whey afford very useful resources. The air, exercise, and clothing of the patient also deserve attention. In mild aperients, as castor-oil, manna, and magnesia, with mild mercurial alteratives and soda, and, if there be any feverishness or fretfulness, small doses of nitrate of potass and the tepid bath, the medical treatment consists. As soon as it can be borne, the ferrum tartarizatum, given in small doses, affords a convenient alterative and tonic. The chloruret of potass and the pyroligneous acid, both in small doses, are said to have been found particularly serviceable in this eruption, as, also, the Peruvian balsam and sulphate of quinia. Nor is the local treatment of the pustules, if large, unimportant. If there be much pain or irritation, fomentations of the decoction of poppy-heads frequently afford relief; in superficial ulcers, with profuse acrimonious discharge and itching, weak solutions of chlorine or chlorate of lime are most useful applications.

**3. Ecthyma Luridum.**—*Syn.* Terminthus (*Auctor. Var.*); Psoride crustaceæ sordide (*Alibert*); *ecthyma chronique* (*Rayer*).

An eruption of large phlyzacious pustules, sometimes acquiring a very considerable size, having their base hard, elevated, of a dark livid red colour, and continuing highly inflamed, even after scabbing takes place; slow in their progress, extensively distributed over the body, and generally connected with a state of cachexy; these circumstances afford the distinguishing features of this species of *ecthyma*, which, though in different stages, is accurately represented in Plate XLIII. of Bateman's *Delineations*, and in Plate LIII. of *Alibert*.

The pustule of this species is more analogous to an ill-conditioned boil, being more extensive and prominent than is usual in *ecthyma*. Suppuration is seldom completed in less than eight or ten days, when the pustules break and discharge a curdy, sanious, or bloody fluid, which is soon converted into hard dark scabs, and these are encircled with a hard violet or livid red-coloured areola. The surface covered by the scabs is slow in healing, and the ulceration sometimes extends beyond the

limits of the pustule; but the ulcerated cavity is soon filled up with hard dark-coloured scabs, firmly attached, seldom separating for many weeks, sometimes not for months. Though the ulceration extends, it is always surrounded by a deep-seated hardness and by a dark inflamed border, and, when not covered by a scab, which sometimes happens if they have been removed by violence, tedious ulcers, with callous edges, discharging a sanious pus, are often the consequence. When the scabs fall off, dark red-coloured patches, or cicatrices of a violet red colour, remain for a considerable time over the parts which have been occupied by the pustules. Sometimes the pustules are long stationary, and do not proceed to suppuration, but are followed by tubercles of a violet colour; these may, however, ultimately proceed to suppuration and ulceration, and thus leave irregular cicatrices in the skin. In this species the pustules are more entirely independent of each other's progress, and may continue to succeed one another without any order for several months. They are often attended with extreme pain and soreness, generally without fever; but sometimes considerable constitutional irritation is present, and in protracted cases hectic fever: in some cases the respiration is remarkably affected.

*Ecthyma luridum* is always a symptomatic affection, a consequence of cachectic disorder of the habit. For this reason, it prevails most during the winter season, and is most commonly met with amongst persons advanced in life, or amongst those whose constitutions have been broken down by misfortunes or imprudence. Hence the indigent who inhabit dark, damp, and narrow streets and cellars, whose means and habits seldom allow them the comforts of cleanliness; prisoners confined to dark and dreary dungeons, filthy, squalid, and ill-fed; those who have been exposed to great hardships and hard labour; or those who have been compelled to live upon unwholesome food, particularly such as is hard, dry, smoked, and salted; and such as have abused their health by an irregular life, particularly those addicted to the use of ardent spirits, are most frequently the subjects of this disease. The state of body which prepares for this disease may also be produced by previous diseases, as in febrile affections, when the cure or the crisis has been imperfect; and in this way it occurs very frequently as a sequel of scarlatina, measles, and small-pox.

The essential point in the treatment of the *ecthyma luridum* consists in correcting the faulty state of habit upon which this disease depends, and this object, the cure of the cachexy, is not to be attained by any one simple method of treatment, but by the combination of several,—neither by depuratives, nor alteratives, nor tonics, but by a happy adaptation and adjustment of them all. The experienced physician knows, that to renew and regenerate the organizing and organizable fluids of the body, before proffering a supply it is necessary to excite a demand, and that to give vigour and activity to the function of nutrition, it is useful to diminish the volume of the nutritive fluid; that, whilst in this way activity is given to the process of nutrition, care should be taken to modify, by the proper use of alteratives, the action of the organs, by whose united functions the

nutritive fluid is created; and that these actions may be performed satisfactorily and effectually, it is necessary by stimulants or tonics to support the action of the nervous system, until the new, fresh, and healthy blood is of itself capable of doing so. In these three intentions, the indications of the cure of cachexy consist. Therefore, in the commencement of the disease, mild cooling purgatives, or very small repeated bloodlettings, (from two to four ounces,) and light nutritious diluting drinks, are good preparatory measures; whilst any distressing irritation may be relieved by opiates, the action of any organ which is deficient may be solicited or modified by its appropriate specific stimulus, and the vigour of all may be increased by exalting artificially that of the nervous system. From this view the practitioner will readily understand the application of such remedies as sarsaparilla, guaiacum, and taraxacum; of saline mineral waters; of antimony and mercury, either alone or as they are more conveniently united in Plummer's pill; of vegetable and mineral acids, of decoction of cinchona, of sulphate of quinia, and chalybeates; of the fresh and sea-water tepid bath and cold sea-bathing; of whey, asses' milk, milk diet; of food, light, nutritive, and easy of digestion; of wine in small quantities; of gentle exercise in open dry air; of warm clothing; and, as much as may be possible, of quiet and repose of mind.

The local treatment, when the state of the pustules demands it, consists in emollient applications and softening plasters to favour a benign suppurative process; but when they show any malignant appearance or disposition to gangrene, it is best arrested by nitrate of silver in solution, the butter of antimony, or caustic potash.

4. *Ecthyma Febrile*.—*Syn.* *Ecthyma cachecticum* (*Bateman*); *Psoris crustacea acuta* (*Alibert*); *Ecthyma aigu* (*Rayer*).

After febrile symptoms of two or three days' continuance, accompanied by headach, pains of the limbs, loss of appetite, disordered digestion, irregularity of the bowels, great restlessness, and sometimes delirium, there appears an eruption of numerous and scattered phlyzacious pustules, generally smaller than in the other species. The pustules are commonly first observed upon the extremities, to which, either dispersed or clustered together in irregular patches, they are sometimes confined; but they also frequently appear first upon the breast, in other cases on the forehead; and sometimes extend over the whole trunk, the face, and the scalp. The eruption of the pustules is accompanied with a burning stinging sensation, or with itching or tingling, and a great desire to relieve it by scratching. After the first eruption fresh pustules continue to break out daily, until the skin is thickly studded with them; and as the successive pustules go through their different stages of inflammation, suppuration, and desquamation, at similar periods after they arise, they are necessarily seen under all these conditions at the same time; the rising pustules exhibiting a bright red hue at the base, which changes to a purple or chocolate tinge as the inflammation declines, whilst little laminated scabs are formed upon their tops: when these fall off, a dark stain is left, which remains for some time. The pus

tules which occupy the breast and abdomen are generally less prominent than those on the face and arms, contain less matter, and terminate rather in scales than scabs. Pustules may continue to succeed each other, in the manner just described, for several weeks, the average duration of the disease being from two to four months. The best representation of this species of ecthyma is that in Bateman's Delineations, Plate XLIV.

On the appearance of the eruption the febrile symptoms are diminished, but not removed, for a state of constitutional irritation, of erethism, or hectic, continues during the progress of the disease, which is invariably accompanied by great languor, and by much depression both of the spirits and muscular strength. The pulse is generally quick and small; the skin hot, dry, and harsh; the tongue dry, red, and glazed; the gums tender, swollen, and bleeding easily, sometimes to a considerable extent; and there is generally an inflammatory state of the fauces and pharynx, in which superficial ulcerations may be observed; this inflammatory state sometimes extends to the Schneiderian membrane and conjunctivæ. The legs and feet are occasionally œdematous.

The ecthyma febrile is always a symptomatic disease depending upon an inflammatory state of the mucous membrane of the stomach, and connected with a digestive state of the abdominal circulation, corresponding to that disorder of body described by writers under the term of scorbutic cachexy. In persons of this state of body this eruption declares itself at the change of season, in spring and autumn, from exposure to inclemencies of weather. It occurs most frequently after the body has arrived at full maturity, particularly in those debilitated by a long series of excesses; and it is occasionally seen in the crude convalescence of gastritis imperfectly cured.

The nature of the ecthyma febrile affords satisfactory indications for its cure. If the eruption be extensive, the local inflammation severe, or if it be attended with much fever, depletion by small venesections, by leeches to the anus, epigastrium, or hypochondriac regions, or by cooling saline purgatives, is a necessary measure; whilst the secretion of the liver is to be solicited by mild mercurial alteratives, taking care to prevent their affecting the constitution,—a circumstance, however, liable to occur in this disease, even from very small doses. The mercurial alterative may be combined with antimonials, as the James's powder, or with Dover's powder. These, with the tepid bath if there be much irritation, diluting acidulous drinks and light diet, constitute the means of cure. In milder cases, cooling saline purgatives and acidulated drinks will, in the commencement, be found sufficient; and when the febrile symptoms have abated, the Plummer's pill combined with a course of taraxacum affords an alterative treatment of great value.

These remedies may be succeeded by the diluted sulphuric acid and preparations of cinchona, as soon as the state of the stomach admits them. The warm alkaline or salt-water baths are very useful subsidiary means, and the diet throughout should be mild, light, easy of digestion and nutritious.

When the pustules are the seat of much pain,

of itching, or uneasiness, local applications are of considerable use. Of these a solution of chlorate of soda is one of the best. Dr. A. T. Thomson found great advantage from the following:

R Plumbi acetatis, ʒss.

Acid. hydrocyan, f.ʒiii.

Unguenti ectacæi, ʒiii.

M. fiat unguentum partibus cutis nudis applicandum.

The ecthyma febrile has only been accurately described by Bateman, Alibert, Hewson (North American Medical and Surgical Journal, January, 1826), and Dr. A. T. Thomson (Bateman's Synopsis, 7th edit. 1829).

5. *Ecthyma Syphiliticum*.—*Syn.* Syphilitide pustuleuse phlyzacrée (Rayer, *Biett*); Pustular venereal disease (*Carmichael*).

Under the influence of the venereal virus, modified no doubt by some peculiarity of constitution, natural or acquired, an eruption of phlyzacious pustules is frequently observed; and which, in a classification founded entirely on the external characters of disease, we are justified in placing under the genus *ecthyma*.

The pustules of the ecthyma syphiliticum succeed each other, are generally sparingly scattered and distinct, and seldom very numerous, and have been by Lagneau, on account of their large size, compared to those of small-pox; they are most frequently seated upon the limbs, and especially upon the legs; but they have been observed upon every part of the body. They first appear under the form of a livid spot, in breadth somewhat less than that of a shilling, but also sometimes larger; throughout a considerable extent of this spot, the epidermis becomes raised and gradually distended by a greyish sero-purulent fluid, whilst the tumefaction slowly increases, and is surrounded by a broad areola, invariably of a livid copper colour, one of the characteristic distinctions of this species of ecthyma. After a few days the pustule opens and discharges a liquid, which concreting forms a very hard blackish or brownish-black scab; the scab becomes by degrees very thick, furrowed circularly, and is generally of a regular round form. The progress of the pustule most commonly takes place without any symptoms of local inflammation; there is little increase of heat; the surrounding parts are free from pain; a slight smarting is all that the patient feels. The scabs are strongly adherent, and they may remain undetached for an indefinite time; but when they fall off, either spontaneously or by means of emollient applications, they expose round ulcerations, most commonly deep, having their edges abruptly precipitous, formed of a hard violet-coloured tissue, and their bottom of a greyish, pale, unhealthy aspect. These ulcerations seldom extend, but the scab gradually forms again, and is successively detached; until at last, by means of appropriate treatment, the new scabs are formed less thick, the ulcerated surfaces become healthy, and are succeeded by a permanent round cicatrix, of a copper colour. (*Cazenave et Schedel*, *Abrégé Pratique*, &c. Paris, 1828.)

Infants born infected with the syphilitic virus present most commonly this form of eruption. In this case the pustules are very numerous, broad, flat, superficial, and of an oval form. They be-

come covered with blackish scabs, of no great thickness, which are followed by small ulcerations. A very characteristic general appearance of the countenance, which it would be difficult to describe, attends this complaint. The skin is foul, the features are drawn, and the whole body is emaciated, wan, and, as it were, etiolated; the countenance is wrinkled, giving the appearance of extreme old age, and a peculiarly diseased odour is exhaled. (*Cazenave et Schedel*, Op. cit.)

The pustules of the ecthyma syphiliticum are distinguished from those of the other species by being surrounded by an areola less broad, but of a dark copper or violet colour; by their thicker scabs, furrowed circularly; by being succeeded by ulcers round and deep, with precipitous edges, and being invariably followed by a depressed indelible cicatrix, and by being generally attended by some concomitant constitutional symptoms, such as inflammation and superficial ulcerations of the fauces, pains of the bones, sometimes *iritis*, whilst the history of the case affords the evidence of some primary affection.

Mr. Carmichael, who is peculiar in his opinions in limiting the true syphilitic disease to one form of eruption, does not consider the phlyzaceous pustules to be of that nature. He considers them as consecutive of a peculiar primary ulcer, which he describes as characterized by a reddish-brown surface, bordering closely on the phagedenic character, having its edges raised and well defined, not excavated, but either on a level with the surrounding skin or considerably raised above it, appearing at its commencement in the form of a small pustule, attended with itchiness. According to his observation the secondary eruption is preceded by fever. (*Carmichael on Venereal Diseases*, 1825.)

The view which Mr. Carmichael entertains of this eruption leads him to consider mercury as unnecessary for its cure; he therefore depends upon antimonials, sarsaparilla, and guaiacum for the constitutional remedies; zinc lotions and rest in the primary affection; sulphur fumigations, or equal parts of tar and sulphur ointment as the local remedies in the secondary eruption. But as this method of treatment has not met with general sanction, the greatest number of practitioners think it safest to have recourse to the specific cure. This has been already described at length under *Acne Syphiliticum*. (See *ACNE*.)

[This form of ecthyma, as well as that which attacks chiefly the legs of old and cachectic persons who have lived intemperately, is well treated by the iodides, especially the iodide of iron.]

When an infant at the breast is the subject of this eruption, the remedy should be introduced through the system of the nurse, either by administering to her the liquor oxymuriatis hydrargyr., or by the friction of mercurial ointment; and if the health of the nurse does not allow of this manner of introducing mercury, the same may be effected by giving the infant the milk of a goat which has been submitted to the friction of mercurial ointment. These methods have been used at the Hospital of St. Louis at Paris, and followed with the most complete success. But the mercury, if necessary, may be also directly given to the in-

fant; either small doses of the hydrargyrum eumcretâ, or minute doses of the oxymuriate of mercury in decoction of elm bark or emulsion of bitter almonds, as recommended by Dr. A. T. Thomson. (*Bateman's Synopsis*, 7th edit.)

T. J. TODD.

ECZEMA, (from *ἐκζέω*, *effervesco*), is a disease of the skin, characterized at its commencement by the existence of minute vesicles, which are usually closely crowded together, and terminate either in the absorption of their contained fluid, or in its effusion and subsequent concretion into thin scales. It is accompanied with a burning heat and tingling of the inflamed portions of the skin. The disease is not contagious, is usually unattended with fever, and may, for the most part, be traced to some irritating cause, either acting directly on the cutaneous surface, or internally through the medium of the constitution.

Willan and Bateman, who have always endeavoured to seize on the earliest appearances presented by cutaneous diseases, as being the most constant and characteristic, have placed eczema in their sixth order, *vesiculæ*; whilst Alibert, whose classification is usually founded on the more obvious, though less distinctive, phenomena occurring in the advanced period of these affections, a period when several species which were originally dissimilar often become confounded in their external features, though still unlike as to their eventual progress, and as to their appropriate modes of cure, has placed it in his order "*dartre squameuse*." Thus he has grouped it along with some of the true scaly diseases, and along with some of the papular ones. Struck, however, by the abundant serous secretion by which it is usually moistened, (and which should have led him to a knowledge of its essentially distinct nature, by turning his attention to its primitive vesicular form, the source of this moisture,) he adds the characteristic epithet "*humide*."

M. Bielt, who, to an intimate acquaintance with the labours of his own countrymen in this department of pathology, adds an extensive knowledge of the works which have appeared on the subject in England and Germany, usually manifests a decided preference for the classification and general views of Willan and Bateman. But in respect to eczema, he thinks these authors have too many subdivisions of the disease, and have spoken in too sweeping a manner of the absence of inflammation around the vesicles, and of fever; as the former almost always exists to a certain extent, and if the local affection occupies much space, some fever usually results. The latter fact, however, we think is very plainly hinted at, if not expressly stated, by Bateman himself. If the cutaneous affection be very severe and extensive, we often also find inflammation of the mucous membranes to coexist.

Rayce, a more recent writer, whose views often manifest a somewhat singular coincidence with those which Bielt has been in the habit of publicly teaching for many years past, emits the same opinion as to the unnecessary subdivision of this affection in the English classification, and proposes to substitute a two-fold division, viz. into *acute* and *chronic*, as more practical and useful

than the triple one into *eczema solare*, *eczema impetiginodes*, and *eczema rubrum*; against which, in addition to the want of uniformity in the grounds on which it is formed, it may be objected that the first and third are really the same disease, differing only in respect to their cause, or the degree of attending inflammation; and against the second, that it is really a complication of two diseases, and not a distinct, well characterized, simple species. Averse, however, to interfere with an arrangement so universally adopted in these countries as that of Willan and Bateman, we shall not here deviate from it, convinced that in pathology as well as in pharmacy, the modern taste for uniformity and simplification of nomenclature, whenever it has deprived us of terms recalling well-marked sensible characters, effects or causes, has tended to do injury to a science so strictly practical as that of medicine. Names that make a strong impression on the memory are here often much more desirable than those whose only merit is their consistency with a purely scientific but unimpressive uniformity.

Ecze<sup>m</sup>a most frequently appears simply as a local disease, preferring, unlike the true scaly diseases, those situations where the sebaceous follicles abound, as the ears, axillæ, groins, upper and inner part of the thighs, scrotum, margin of the anus, and in women, moreover, the external parts of generation, the nipples, and adjacent portions of the breast; or it selects those parts which are much exposed to external influences, as the hands, arms, and face. At times, however, it is a much more extensive disease, and occupies successively nearly the whole cutaneous surface; and this is especially the case when it originates in the use of mercury, or in some other cause acting through the medium of the constitution.

1. **Ecze<sup>m</sup>a Solare** chiefly occurs in persons of a delicate skin, after long exposure to the rays of a summer sun. Sportsmen, and those who take very long walks in this season, mowers, harvest-labourers, and others whose business exposes them to the above cause, are its most frequent subjects. It is occasionally preceded by a slight feeling of general indisposition; and some degree of tension, together with heat and tingling, is felt in the portion of skin which is to be the seat of the eruption. This is most commonly the backs of the hands and fingers, and the face, neck, and arms, especially in women, or those who happen to have them long uncovered whilst in the sun. The skin is usually pale, and is crowded with thick-set microscopical vesicles, so closely approximated as to leave no interstices of redness. Occasionally, however, there is a slight blush round each vesicle; and this species occurs usually, as Bateman mentions, in the upper part of the arms or on the breast, particularly in females, and is commonly called *heat spots*. In men of a sanguineous temperament who use violent exercise in hot weather, phlyctenaceous pustules, or painful and slowly suppurating tubercles not unfrequently make their appearance in the midst of the eczematous eruptions.

The vesicles are very small and acuminated, and contain a limpid fluid, which soon becomes milky and is absorbed; or after slightly increasing in size, they burst and effuse their contents, which concrete and form minute brownish yellow scales

or scabs, and the whole disease, if not very extensive, finally terminates in desquamation within one or two weeks from its commencement. The larger the surface at first attacked, and the greater the irritation, the more likely is the affection to spread successively to new and extensive portions of the cutaneous superficies. Some precursory indisposition, as we have just stated, may occur, but much more frequently it is absent, the eruption coming out almost immediately after exposure to the sun's rays. It usually begins and terminates in an acute form, but at times it passes almost immediately into a chronic inflammation, with an abundant exudation of a viscid fluid, which rapidly concretes in the form of thin scales, and is attended with tenderness, redness, and excoriation of the affected skin. In these prolonged cases, as Bateman remarks, the effused fluid seems to be of an acrid nature, inducing inflammation, and occasionally superficial ulceration of the parts with which it comes in contact, and the disease assumes somewhat of the form of impetigo. The duration of this affection seems to be little under the influence of medicine, and usually requires little more than the protection of the part from the exciting cause, and the frequent employment of tepid ablutions.

2. **Ecze<sup>m</sup>a impetiginodes** is preceded and accompanied by a painful tension, formation, and pruritus, and is distinguished from the other varieties by the occasional intermixture of pustules, into which its vesicles, which are deeply imbedded in the skin, become themselves not unfrequently converted. All this gives it a considerable resemblance to some of the forms of impetigo, to which it is also allied in the similarity, or rather the identity, of its causes, which for the most part consist in the habitual contact of various irritating matters. Thus the irritation induced by the repeated application of lime, sugar, alkalies, &c., to the hands, gives rise to eruptions, (bricklayer's itch, grocer's itch, &c.,) which are vesicular in some individuals and pustular in others, and are apt to assume a chronic form when the exciting cause long continues to be applied. Thus, also, either a vesicular or a pustular inflammation may be induced by the irritation of sulphur or sulphurated alkalies, used for the cure of common itch, and be mistaken for the continuance of this disorder.

Similar eruptions may be caused by a blister, a mercurial plaster, Indian varnish, valerian root, diachylon, frictions with croton oil, opodeldco, or ammoniacal liniments, and many other stimulating external applications. Exposure to the heat of a forge or a strong fire has sometimes excited it, as has likewise the internal use of various medicinal substances, as opium, antimony, copaiba, &c. Irregularities in diet and excessive drinking are also reckoned amongst its occasional causes. When the skin is very delicate, this eruption has been known to manifest itself within three or four hours after the application of a Burgundy pitch plaster, and to be productive of much distress. We have known an individual in whom almost every species of plaster, even the mildest and least irritating, has given rise to this affection, and have seen it ensue in another after the employment of the common linseed poultice. The mixed erup-

tion of vesicles, pustules, and boils occasionally induced by a blister or other irritating plaster, often extends to a considerable distance from the centre of irritation, overrunning a considerable portion of the chest, back, abdomen, &c., inducing much pain and feverishness, and persisting occasionally, as Bateman remarks, for a fortnight or upwards, but without any eventual injury.

The eczema impetiginodes, if its extent be not great, may run through its course in from one to three weeks. Occasionally, however, it passes into an obstinate pustular or sealy disease, and this we have seen it do within a fortnight after its commencement. In its ordinary course, the vesicles break and discharge an acrid fluid that irritates the adjacent skin, which becomes inflamed, thickened, fissured, and excoriated in streaks, as if torn by the nails. At this period its resemblance to impetigo is still more striking than at an earlier stage.

In the treatment of this affection, in addition to the removal of the irritating causes, and the use of the antiphlogistic and local soothing measures to be detailed at the end of this article, we must at the same time endeavour to remove that morbid state of the system of which the proneness to these eruptions from slightly irritating causes is an evidence; and it is in this part of the treatment of cutaneous disorders that the French practitioners, who have anticipated and excelled us so much in the employment of the antiphlogistic and soothing measures just alluded to, appear to have fallen short; the proper attention to the regulation of the functions of the digestive organs being too often overlooked by them. The most remarkable instances of this extreme irritability of the skin which we have met with, have been in individuals labouring under dyspeptic symptoms of an old date; but we do not by any means wish to insinuate that this is universally the case. Eczema impetiginodes, as well as impetigo itself, seems to fall under the head of *durle squamneuse crustacée* in Alibert's arrangement.

3. **Eczema rubrum** is the most severe and most inflammatory variety of this affection, and is, like the others, preceded by a feeling of stiffness, heat, and tingling. It takes its specific name from the diffuse or erythematous redness on which the vesicles make their appearance. At first it has somewhat of the appearance of erysipelas, but may be easily distinguished from it by the roughness which it presents to the touch, and which, on minute examination with a lens in a favourable light, is found to depend on the presence of innumerable small and crowded transparent vesicles. These in two or three days become opalescent, and in size about equal to a pin's head, after which they usually burst and pour forth their contained fluid, which inflames and excoriates the parts with which it comes in contact. The disease successively invades new portions of the skin, and is accompanied as it proceeds with swelling of the true skin and cellular membrane. The discharge from the vesicles is often very abundant, has a peculiarly heavy odour, and concretes rapidly into yellowish incrustations. Hardening on the patient's linen also, it causes much

pain, by coming in contact with the excoriated surface, which in some cases is so extensive as to occupy the greater portion of the body. When so widely spread and severe, it causes much suffering, and a certain degree of febrile excitement is necessarily the consequence.

It usually makes its first appearance about the scrotum or inner part of the thighs or groins, but this is not constant. Its duration is indefinite. If limited in extent, it may run through its course within a fortnight; but if it has occupied the greater part of the surface of the body, it may last for a couple of months or even longer, when at length the encrusted secretion drops off. But the morbid cuticle continues to exfoliate for a considerable time after, and this is occasionally attended with the loss of the hair and nails. Of this affection, mercury is one of the most frequent causes. The *mercurial eczema* (sometimes misnamed erythema) seems to have been first clearly noticed by Benjamin Bell, in his treatise on Gonorrhœa and Lues Venerea, and was subsequently more fully investigated by Dr. Moriarty, Dr. Spens, and Dr. M'Mullen, and by Mr. Alley and Mr. Pearson.

Dr. M'Mullin's description of it, in the second volume of the Edinburgh Medical and Surgical Journal, represents it as a much more serious affection than Bateman and most succeeding writers have done. According to Dr. M'Mullen, it is ushered in with a well-marked febrile paroxysm, and is accompanied by dry cough, difficult respiration, and sense of tightness across the præcordia—the skin being remarkably hot and the seat of an itching and prickly sensation. On the first or second day, a diffused redness and numerous crowded papulæ (vesicles) make their appearance, generally on the scrotum, thighs, or forearms first, or on those parts where mercurial frictions have been made. The cuticle soon exfoliates, and the fauces and eyes become somewhat inflamed. The above symptoms, which, according to Dr. M'Mullin, characterize the first stage, last for one or two weeks, and if the disease be in a mild form, recovery may ensue immediately after the desquamation; but if severe, a second and much more serious stage ensues, in which the skin is studded with innumerable vesicles, which soon discharge an irritating fluid of a nauseous odour. This, by concreting into large incrustations of a reddish or dark colour, constitutes the third stage. The inflammation of the fauces, eyes, and eye-lids now becomes exasperated, and the face is deformed by a mask of encrustations fissured in various directions. The affection occupies successively a large surface of the body, which in its excoriated state is the seat of great irritation, and the pain is exasperated by the weight of the body in lying, as well as by the contact of the concreted matter. The latter is liable to crack or be torn across on the slightest change of posture, and thus new raw surfaces are continually becoming exposed. A fever of the typhoid type accompanies these extreme cases; yet, which is singular, the appetite continues unimpaired throughout. The catarrhal symptoms generally undergo an exacerbation towards the conclusion, as is manifested by the increased anxiety and pain in the chest, the cough, and bloody expectoration. The pulse becomes

frequent, feeble, and irregular, the tongue black and parched, and diarrhœa, delirium, convulsions, gangrene of the skin, and death close the scene.

In the above description we scarcely recognize the comparatively mild disease described by Bateman, whose account certainly agrees much more closely with the affection usually met with in practice.

In mercurial eczema, in addition to the catarrhal affection of the air-passages, a tendency to inflammation in the mucous membrane of the intestines often coexists, as is manifested by the facility with which diarrhœa is induced. Dysury too is an occasional but much rarer symptom. The catarrhal affection is not mentioned by Bateman; and by some other writers, who speak of it, it is considered to be merely a casual complication. Dr. Gregory thought that both the affection of the skin and that of the mucous membrane were the effect of cold caught whilst under mercurial influence; but Mr. Pearson's experience does not confirm this opinion. Rayer strangely intimates that the occurrence of eczema mercuriale may be obviated by taking the precaution of shaving the part to which mercurial frictions are to be made. When we recollect, however, that it may be induced by almost every form of mercurial medicine, and that too whether internally or externally administered, we cannot place much confidence in this mode of prevention. That inflammation of the skin should result from the internal exhibition of mercury, is in no respect more wonderful than that severe and even fatal enteritis should originate in its external employment, as in the instances recorded by Dr. Crampton.

Those cases of eczema rubrum which originate in the use of mercury, are generally the most extensive. Local examples of it on exposed parts seem to be sometimes induced by the influence of very hot weather, and a succession of red patches generally make their appearance in such a manner as to prolong the disease to several weeks, without, however, any evident derangement of the general health. Amongst its occasional causes have been reckoned, a stimulating diet, the constant use of shell or sea-fish, &c. Some individuals are subject from slight or inappreciable causes to a very frequent recurrence of this affection about the ears, face, and back of the neck, accompanied with swelling and redness of the face, and a considerable fullness about the eyelids; which obtain for it in popular language, but very improperly, the appellation of erysipelas, from which it differs both in its duration and the degree of danger attending it, as also in the presence of vesicles in place of bullæ. Occasionally minute pustules are intermixed with the vesicles, and make the eruption approximate more closely to the description of the impetiginous variety of eczema.

Eczema in its chronic form, which often proves a very intractable disease, (its removal, especially in elderly persons, being attended with great difficulty, and its relapses frequent,) has perhaps not been sufficiently attended to by Bateman.

According to Rayer, who has given an excellent description of it, it may occur as the sequel to any of the acute varieties above described. In it the inflammation often extends deep into the true skin

and cellular membrane, giving rise to a thickening, roughness, and inequality of the surface, which becomes fissured and excoriated, and is not unlike a part which has been lately blistered; being raw and moist in some points, and presenting a scurfy appearance from adherent cuticle or dry and foliated secretions in others. It is in this advanced stage of eczema that its identity with the *dartre squameuse humide* of Alibert is most obvious. The secretion of acrid lymph is uninterrupted, and the itching so intolerable, that the unfortunate patient cannot abstain from tearing the surface with his nails, and thus aggravating and perpetuating the disease.

This state may continue with little variation for months or even years; the cuticle, which assumes a yellowish tinge from the contact of the discharge, being at frequent intervals exfoliated in large patches. The inflammation is liable to frequent exacerbations; and occasionally, after appearing to be almost subdued, it bursts out with increased violence, either on the same place, or in some distant part of the body.

One of the most frequent seats of chronic eczema is about the external ears, and from thence it not seldom extends into the meatus auditorius externus, and thus sometimes induces deafness. In like manner, when it exists on the face, it may spread from the external surface of the nose to the nostrils; and in both this and the preceding case it proves peculiarly obstinate. When seated on the lips, they occasionally become considerably swollen, and we have seen it in this state present an appearance which might in young persons have been mistaken for a scrofulous affection. When it attacks the scalp, it is not unfrequently confounded with tinea. There is great itching. The hair is at first matted together with the abundant discharge, but this, gradually diminishing, is succeeded by a constant furfuraceous desquamation, beneath which the skin on examination is found to be red, shining, and tender.

In its chronic form, eczema frequently manifests itself also on the upper and inner part of the thighs; the scrotum and prepuce in men, and about the external organs of generation and the breasts in females; and in all these situations the itching is most intolerable.

The circumference of the anus is also very frequently attacked with it, simultaneously or alternately with other parts of the body. It often occurs here by an extension of the disease from the scrotum or thighs; but in some of the most obstinate examples it is a strictly insulated affection, confined to the verge of the anus, perineum, and cleft of the buttock; in which situations a serous secretion concreting into thin, laminated, semi-transparent scales, like exfoliated cuticle, takes place at intervals. In these cases it seems often to be connected with dyspepsia and an irregular state of the bowels, the stools being unnatural, and affording evidence of vitiated intestinal and biliary secretion, inasmuch as they are often peculiarly fetid, black, and tenacious, and expelled with so much difficulty, as to give rise to the belief in the existence of a stricture of the rectum. But this difficulty seems to depend merely on a spasmodic state of the sphincter, induced by the chronic irritation in the skin and contiguous portion of the

mucous membrane of the rectum; for the patient is at times able to evacuate the bowels freely. The empirical use of bougies in such cases cannot fail greatly to aggravate the patient's sufferings and perpetuate the evil, by the forcible extension of the excoriated parts. The sensation of burning heat and itching becomes greatly aggravated on getting warm in bed, demanding all the resolution which the individual can summon up to avoid scratching and exasperating it with his nails, an operation which in his sleep almost inevitably takes place. The exacerbations to which this affection is liable sometimes alternate and sometimes coincide with those of the dyspeptic affection. It is one of the many examples of the intimate sympathy which subsists between the external outlets of mucous membranes and the more internal and distant parts of their surface. *Ascarides* sometimes coexist with this disease, and though there is no reason to suppose them capable of producing it, save when a peculiar predisposition exists, they must doubtless tend much to exasperate the irritation and prolong its existence. We have known this affection alternate with small patches of lichen, psoriasis, or eczema on the arms or neck. Sedentary habits, too free a mode of living, especially in regard to the use of wine and malt liquors, and costiveness, are sure to aggravate it. With regard to the treatment of it, little can be expected from local applications; frequent ablution with cold water affords a momentary relief; but it is to great temperance, steady and active exercise, a due regulation of the bowels, and a correction of the vitiated and irritating nature of the alvine discharges, that we can alone look for permanent benefit.

The **diagnosis** of eczema is occasionally attended with considerable difficulty, as cases not unfrequently present themselves where papulæ and pustules coexist with the true eczematous disease; thus allying the case at once to lichen, impetigo, and eczema, and making us wish that the idea of Burns had been acted on, in establishing as an appendix to our present classification a set of composite genera to which those specimens of cutaneous disease which are of a mixed character, and display an affinity to two or more of the simpler forms, might be referred. For the consolation of the student in this department of pathology, we may mention that we have seen the most practised eye puzzled by such combinations; and individuals, who had made cutaneous disorders their peculiar study for years, confess themselves unable to dispose satisfactorily of such examples in any part of our present arrangements.

In the first stage of the affection, when it exists in its simple form, the only diseases with which we are liable to confound it are some of those of the papular kind, and scabies. From the former it may be satisfactorily distinguished by the colour of the minute vesicles, or more certainly still by puncturing them with a needle, and thus demonstrating the fluid nature of their contents. Their subsequent progress, too, is dissimilar. From scabies, or common itch, the diagnosis, especially of the impetiginous form of eczema, notwithstanding what is asserted by professed writers on the subject, we have often found by no means easy. Its preference for those situations where

the sebaceous follicles abound—a knowledge of the preceding causes, such as exposure to great heat or other local irritants—the closeness and uniformity with which its minute and acuminate vesicles are distributed,—the accompanying tumefaction—the tingling and smarting rather than itching which attends them—will, it is said, enable us to distinguish it from the scabies, in which the vesicles are more apart—larger and more unequal in size—less transparent, or of a duller colour, and without any inflammation at their base,—intermingled with minute ulcerations and small dark scabs—attended with a sensation of simple itching—and, finally, occupying chiefly the intervals of the fingers, the wrists, and the flexures of the articulations generally.

The presence or absence of a contagious quality, and the effects of treatment, which are usually dwelt on as points of distinction, are not very creditable grounds on which to form our diagnosis. To discover the nature of a disease when it has been already cured, or when it has spread to other persons in consequence of our incompetence to decide on its true nature, is not satisfactory to any of the parties concerned.

A complication of itch and eczema is not an impossible occurrence, and of course must present much difficulty. Indeed, we have heard of such cases by which the medical attendants were greatly embarrassed, till in the frequent handling and examination of the parts they have themselves contracted scabies, and thus become fully convinced of the existence of at least one part of the disorder.

The milary eruption may be easily distinguished by the constitutional symptoms which precede or accompany it; and simple erythema, by the absence of all feeling of roughness such as characterizes eczema rubrum even in its early stage, and depends on the elevation of the nascent vesicles. Inattention to this circumstance has led some writers improperly to describe the eczema mercuriale as a species of erythema. Impetigo is sometimes distinguishable with difficulty, if at all, from that species of eczema in which pustules present themselves. The existence of pustules from the very commencement, and the greater thickness and prominence of the crusts, belong more especially to the former. In a practical point of view, however, their diagnosis is not very important. It is often far from easy to distinguish psoriasis of the scrotum and penis from eczema of the same parts when in its advanced and scaly stage: the greater thickening and hardness of the integuments in the former, and the fact of vesicles or humidity never having been present, will aid our diagnosis. When eczema has existed a considerable time, its red, chopped, and scaly surface approximates closely to the appearance of lichen agrius. But even when vesicles no longer exist, as is the case in the more advanced and drier stages of eczema, minute disseminated scaly points will frequently show their former seat, and disclose the true nature of the disease. Eczema of the breast and nipple in its scaly stage, which it has generally attained to before we are consulted, presents to the eye merely a collection of thin and generally yellowish crusts, and is accompanied with a burning itchiness; at this period we should

in vain search for vesicles. Chronic eczema, indeed, in its later periods, when it has passed into a scaly state with numerous erosions and ulcerations, is scarcely recognizable at first sight, even by the most experienced eye. It is to the history of the case that we must here look for decisive information.

In what we have said of the diagnosis of this very frequent and very distressing cutaneous affection, we have been actuated by a desire to represent it in all its true difficulties; as we know that the most zealous students often turn with disgust from the investigation of diseases of the skin, upon finding these difficulties so infinitely greater than they are represented in books, and begin in despair to suspect that they want the tact necessary for their successful study. When made aware of the obscurity which they often present even to the most experienced, this cause of discouragement will in some degree be done away with.

The **prognosis** of the acuter forms of the disease, especially when they depend on some obvious cause of local irritation, is generally favourable. In those cases where the mercurial eczema has assumed its most formidable aspect, the danger has been attributable probably not so much to this affection in itself as to the cachectic habit of the patient, exhausted by previous and co-existent disease as well as by the profuseness of the discharge. In the majority of those instances where chronic eczema is very obstinate, and where the most carefully adapted local treatment has proved unavailing, we should be led to suspect that there is something materially wrong with the state of the general health. We have seen such cases which had existed for years, and resisted for nearly as long a time the most judicious and energetic topical measures. In the aged it is peculiarly unmanageable, and a cure often almost hopeless. Alibert speaks of the *dartre squameuse humide*, in its aggravated form, as one of the most obstinate and insufferable diseases to which humanity is liable; the irritation which it keeps up, and the despondency which innumerable relapses tend to generate, having in some instances, according to him, led the unfortunate patient to the commission of suicide.

**Treatment.**—The introduction of the soothing plan of treatment constitutes the most remarkable improvement which has taken place in regard to the management of the cutaneous diseases in these latter times. In mild cases, if we can succeed in subduing for a time the irritation which exists, nature will often do the rest, and re-establish the natural actions of the part. In no class of these diseases are soothing measures more called for than in the vesicular forms, in which the inflammation is usually characterized by considerable acuteness and a high degree of irritation. This is peculiarly the case with some of the varieties of eczema.

Great relief may usually be afforded by frequent ablution with tepid water or mucilaginous decoctions, as those of bran, marsh-mallows, poppy-heads, or of gruel or milk and water; by mild poultices, with or without the addition of goulard, and by local and general tepid baths. Mr. Plümbe condemns in strong terms the use of ointments,

and recommends the employment of the common spirit-wash in incipient cases. Lotions containing prussic acid have been found to have much influence in allaying the pruritus. When the patient is young and of a sanguineous temperament or plethoric habit, venesection should not be neglected, and leeches and cupping in the vicinity of the disease are most important auxiliaries. The diet should be light and very sparing. Bateman recommends the use of bark and serpentaria, but on no very clear indications. Mild diluents, gentle laxatives, and the use of the vegetable or mineral acids, are generally all the internal medicine necessary, especially in the acuter and more rapid forms of the affection. As to the propriety of the employment of acids, so usually recommended in cutaneous disorders, we might, if guided by theory alone, have some doubts; for in certain habits, as has been remarked by Sir A. Carlisle, they of themselves occasionally excite much irritation in the skin. Thus many people are affected with pimples shortly after taking them, together with burning heat in the face and itching over the whole body. Yet here, as elsewhere, preconceived notions with regard to the propriety of a therapeutic agent in disease, derived from a knowledge of its influence in a state of health, must not be put in competition with the practical results of experience, and we have certainly seen very troublesome cases of eczema yield rapidly whilst acid drinks were used. The mineral acids (sulphuric and nitric) seem, indeed, to have considerable influence in the later periods in diminishing both the exudation and the itching of the affected parts; whilst in the earliest and most inflammatory stage those of the vegetable kind, on account of their cooling properties, perhaps deserve the preference.

In the mercurial eczema, if its attack be violent, Biett, we believe, never omits the precaution of taking blood from the arm, as the best means of obviating or moderating those symptoms of irritation in the mucous membranes of the respiratory and digestive organs which occasionally complicate it. Pearson recommends the use of diaphoretics; but the irritable state of the stomach and bowels frequently renders them improper: and in those very rare cases where typhoid symptoms supervene, the employment of bark will often, for the same reason, be found inadmissible. Opiates have very usually been recommended by way of allaying irritation and procuring sleep, but their exhibition requires much circumspection, as opium has occasionally been known, in this as well as in the healthy state of the skin, to induce severe itching: and Dr. Moriarty met with one case in which it apparently was the cause of a relapse. The daily use of the tepid bath usually affords much relief by removing the secretion and keeping the surface pliant. Where, however, the excoriations are very extensive, even the tepid bath cannot well be borne, and the effort of getting in and out of it causes much suffering. The heat of the bath must be carefully regulated, for if of too high a temperature, it will inevitably aggravate the inflammatory tendency in the cutaneous surface. The pain caused by the rigidity and contact of the incrustations may be in some degree alleviated by the application of the linimentum calcis. Repeated changes of the linen are indispensable, and

will sometimes, from the abundance of the secreted matter, be necessary as often as three or four times in the course of one day. The return to mercury in these cases is to be avoided if possible; as even its mildest preparations have occasionally induced a recurrence of the disease, an effect which took place in a case recorded by Dr. Crawford, from the incautious application of citrine ointment to the still morbid skin. In some urgent cases, however, mercury has been again exhibited, and with impunity.

When eczema has become chronic, the local treatment should still in almost every case be of the soothing kind. Hence a steady perseverance in the use of tepid mucilaginous decoctions, of lotions containing the acetate of lead, of local and general baths, continues, as in the first stage, to be proper. General and local bloodletting and other *antiphlogistic* measures will still often afford us most valuable assistance in subduing this obstinate affection; the propriety of their employment and repetition being of course determined by a joint consideration of the state of the constitution and of the local inflammation in each individual case. We cannot, however, help thinking that, in this country at least, the utility of these measures has, till within these very few years, been greatly overlooked, and that their employment, even at the present moment, is quite too infrequent. This may perhaps in a great degree be attributed to their never once being alluded to by Bateman, whose bias seems to have been altogether towards the opposite mode of treatment, or the frequent exhibition of tonics. His prepossession, too, against the use of aperients in eczema is not justified by the experience of others, as they are often found to be highly beneficial. We have known very severe cases yield to the combined employment of baths, mineral acids, and laxatives. When these and the other measures detailed above disappoint us after having been fairly tried for at least three or four months, recourse may be had to the cautious use of Fowler's solution, or of tincture of cantharides. Amongst Biett's numerous cases under the influence of those powerful medicines, we do not recollect to have seen them ever do mischief; and hence we participate fully in the sentiment with which he frequently prefaces their prescription, namely, that no medicine, however active, is dangerous in prudent hands. Mucilaginous and diluent drinks enter largely into all his plans of treatment, and must tend materially to obviate the danger of gastric irritation during the use of energetic internal medicines. Whether the beneficial influence which arsenic and cantharides often display depends on their immediate action on the skin, or whether it is attributable to their effecting a species of counter-irritation on the mucous membrane, and a consequent equalization of the circulation in the cutaneous and mucous surfaces, is utterly unknown. Their great power as modifiers of the actions of the skin is, however, indisputable. The exhibition of fractional doses of the corrosive sublimate also, given in a decoction of dulcamara, occasionally effects a cure where other measures have failed.

Caustic applications, as the nitrate of silver or diluted muriatic acid, have sometimes been used, as is mentioned by Rayer, with a view to chang-

ing the mode of irritation in the part; but they are not unattended with risk, and violent exacerbations and deep cicatrices have resulted from their employment. In the advanced scaly stage stimulant applications have sometimes been of use, by exciting a more active inflammation, and thus subverting the existing morbid action. Ointments containing the red precipitate or tartrate of antimony, and blisters have occasionally been had recourse to with this view, and with success; but the practice is rather empirical, and the result dubious. In an indolent and scaly state, alkaline and sulphur baths may perhaps sometimes be useful; but if too early employed, they are sure to aggravate the inflammation, and in the great majority of cases the vapour bath is to be preferred to them.

When there exists any obvious derangement of the general health, little improvement need be expected till this state be first counteracted. Country air and a careful regulation of the diet are here points of the first importance; alterative doses of calomel or blue pill, with the decoction of sarsaparilla, will sometimes also be of great service. In those cases where there is a marked inflammatory diathesis, indicated by a full pulse, heat of skin, thirst, headach, drowsiness, &c., Dr. Elliotson has found much benefit from mercurial medicines, given so as slightly to affect the mouth, in conjunction with venesection and a low diet. Such a mode of employing mercury, in a disease of which it is itself an occasional cause, will, however, demand great circumspection.

The use of water-dressings, in preference to all ointments and greasy applications, has long been zealously advocated by Dr. Macartney, who has directed much of his attention to the study of diseases of the skin. Indeed the beneficial effects which may be produced in this and several other cutaneous inflammations, merely by keeping the inflamed part constantly moist by means of lint wetted either with cold water or a weak solution of the acetate of lead, and enveloped in oiled silk, are unquestionable and striking. We do not, however, think that the employment of ointments is in all cases injurious, having known eczema of the ears and face, though attended with extreme irritation, receive immediate relief, and get speedily well under the use of an ointment composed of cold cream and the liquor plumbi acetatis in the proportion of two or three drops to the ounce, in conjunction with the repeated application of a cooling lotion, consisting of the acetate of ammonia, accurately neutralized, largely diluted, and holding a minute portion of the acetate of lead in solution.

If the disease have existed about the face for a considerable time, an issue or perpetual blister to the nape of the neck or the arm effects a useful counter-irritation, and will thus often tend both to accelerate the cure and to prevent a relapse. A free state of the bowels and a frequent use of the bath seem also to have much influence in guarding against a recurrence of the affection.

The propriety of a cooling and sparing diet throughout every stage of the disorder, and even for a considerable time after its disappearance, cannot be too strongly insisted on.

W. B. Joy

**EDUCATION, PHYSICAL.** Education, in the ordinary acceptance of the term, refers only to intellectual and moral cultivation. Mr. Locke, however, has taken a wider and juster view of the subject, and in his excellent Treatise inculcates strenuously the attentions necessary for preserving and strengthening the bodily constitution. This branch has been denominated *physical education*.

If medical science effect something more than the mere adaptation of remedies to a few special diseases; if it embrace the more enlarged and comprehensive purpose of promoting general health, and preserving the bodily frame in the full and vigorous exercise of all its functions, then is the subject of physical education entitled to a prominent place in every work which professes to treat of the science, or to display its most useful applications. No applications of its principles can be more useful than those which regulate the physical management of the young; for even in infancy, and still more when childhood passes onward to adolescence and puberty, are errors of ignorance and prejudice daily committed, which sow deeply the seeds of disease, consigning many a sufferer to an early grave, or entailing miseries which render life a burden rather than a blessing. However difficult it may be to correct the manifold errors by which, in early life, health and happiness are sacrificed, it must at least be right to point out to those who wish to learn, what are the principles by which the first of earthly blessings, a sound mind in a sound body, can be best insured. With bodily health, mental is here associated, for the connection is intimate: if the body languishes, the mental powers, which act only through bodily organization, must fall far short of that energy and activity of which they would otherwise be capable; while the irritability of mind to which weakness and ill health are prone, is sure to act unfavourably on all the moral feelings. In the present article the design is to lay down principles rather than rules; for the latter never can be so framed as to admit of universal application, and when indiscriminately used, they either, through necessary variableness of effect, fail to inspire confidence and in time fall into disuse, or the good which they do accomplish is sure to be balanced by a portion also of evil. To lay down principles is the safer and better course, for though physiological truths are what few even among the most intellectual classes of society are prepared to comprehend, their education unhappily leaving them utterly unacquainted with the structure and functions of their own frames, still the dissemination of these truths, especially in connection with a subject of such deep and universal interest, may not be wholly unavailing, but may rather prove the means of exciting enquiry, and of dispelling that ignorance to which so much of the ill health of every period of life may be distinctly traced.

Man, in his relation to external objects, is subjected by nature to certain laws; in other words, there exist between man and the external world certain definite and immutable relations, as obligatory as a positive ordinance. If the relation be disregarded, the law violated, the penalty ensues with a certainty that cannot be evaded. It is well,

then, as all are subjected to these laws, are capable of acting in conformity with them, and sure to suffer when betrayed, whether by ignorance or wilfulness, into infringing them, that some consideration should be bestowed on them, in order that errors of ignorance at least may have some chance of being avoided.

The natural laws which connect man with the objects around him have been appropriately classed under three heads; namely, the physical, organic, and moral. Vitality confers no exemption from the laws of matter and motion. To these the human body is subject equally as if it were not endued with life. It is true that, while animated, it possesses to a certain extent powers capable of modifying their operation; still it never ceases to be under their influence, and it is liable to suffer whenever that influence is overlooked or miscalculated. The body gravitates, and when deprived of support falls to the ground, equally as if it were inanimate. Physical laws, therefore, are worthy of consideration, in order that no injury may accrue from their violation. But animated bodies are subjected to laws peculiar to themselves; and as life is always connected with organization, these laws are called organic. It is with them that we are more immediately concerned on the present occasion. Man, however, is not only an organized and animated being, but also a moral and intellectual one; and is, in consequence, subject to further laws in relation to this part of his nature, namely, the moral. As his moral and intellectual powers, however derived essentially from his spiritual nature, are dependent on organization for their exercise and manifestation; as the several powers act interchangeably on each other; and as a close analogy resulting from this connection subsists between the organic and moral laws, it will be necessary to take some notice of the latter in the following pages.

The organic laws may be subdivided according as they regard respectively the preservation of the species and of the individual. The former of these may here be passed over as not essential to the present purpose, the preservation of the individual being that which chiefly claims attention in discussing the principles of physical education.

The animal body is connected more immediately with the external world by digestion and respiration, it being through these processes that it derives the elements by which it subsists. Food and air are indispensable so long as life endures; and if either be withheld, or depraved in quality, or too scantily supplied, the animal languishes and prematurely dies. Other elements are most probably combined; there being reason to believe that the electric conditions of the atmosphere exert an influence on the animal economy neither slight nor unimportant. We know too little, however, on this subject to make it the groundwork of any reasoning.

On the regulation of diet much of the health of the body depends. All animals are destined by nature to feed on particular aliments, for digesting and assimilating which they are furnished with an appropriate organization. Some are herbivorous, some graminivorous, some carnivorous. Man being by nature omnivorous, a mixed diet of animal and vegetable food is best fitted for his adequate nutri-

tion, being most accordant with his organization ; and this fact ought to serve as a sufficient reply to all those who decry either animal or vegetable diet. The proportions best suited for supporting perfect health must ever vary in individual instances, being dependent on age, temperament, habits of life, state of health, climate, season of year, and other incidental circumstances. The general principle being clear, sufficient ground should be specially shown whenever it is deemed necessary to depart from it, or to modify its application. To display the properties of the several articles of food, both animal and vegetable, is the province of dietetics. (See DIETETICS.)

The quantity of food deserves as much consideration as its quality. It should be such as the stomach can easily digest, and sufficient to repair the waste which the body continually undergoes. In the young, too, it should provide for the growth of the body, which in them is, up to a certain age, progressive. Deficiency of sustenance leaves the body imperfectly nourished, checks its natural growth, and begets various diseases marked by debility. Excess, on the contrary, promotes inordinate nutrition, induces corpulence, oppresses all the functions of life, and through the various efforts made by the constitution to dispose of or to get rid of it, lays the foundation of by far the greater portion of human maladies. In the functions more immediately essential to mere animal existence, nature influences by feelings antecedently to any exercise of reason, and, with respect to the nutrition of man, has given him appetite both to incite him to take food, and to assign a limit to his use of it. A healthy stomach, supplied with simple diet, will, if the intimations of appetite be heeded, be rarely guilty of excess. But though the stomach is thus satisfied, and the natural appetite ceases, it is still capable of taking more food, and even of digesting it. Viands tempting to the palate will incite a fresh appetite, under which the quantity of food required for health, and which consistently with health ought not to be exceeded, is often more than doubled. Pampered with luxuries, and rather *living to eat* than *eating to live*, numbers become slaves to a sensual gratification of the lowest kind.

Excess is the vice rather of adults than of the young, who are rarely either gourmands or epicures, unless through the fault of those who rear them. The law of temperance, however, is common to all, and, however it may be disregarded by the inconsiderate or the sensual, cannot be violated with impunity.

Co-ordinate with nutrition, in its being essential to animal life, is respiration. It differs in one respect, that while food is required only at intervals, appetite being the natural incitement and measure of quantity, air is necessary every moment ; and as the process goes on uninterruptedly, no incitement of appetite is needed for inhalation of air. The capacity of the lungs, too, being definite, no intemperance can be practised ; and with regard to this function it is quality rather than quantity that requires to be attended to. This, however, is of the very first importance ; for if pure air be not breathed, health cannot be preserved. Of injury from impure air the young are peculiarly susceptible, and this requires to be

attended to in many parts of their ordinary management.

Next in importance to food and air, as a means of maintaining health and vigour, is exercise, which is to be considered not merely as it regards locomotion, but as applying to all the actions of the animal frame which minister to existence, and by which the several functions are sustained. The actions immediately essential to existence are, happily, independent of the will, and are thus secured against the effects of indolence or caprice. Respiration, though not wholly an involuntary process, is so far independent of the will for its ordinary exercise as to continue uninterruptedly, through the whole period of life, without effort and almost without consciousness. Thus circumstanced, and secured as its organs are by their compact and admirably constructed mechanism, it might be conceived that this process at least might escape the evil influences of heedlessness or error ; yet no function of the frame has suffered more from the pernicious effects of folly and fashion, effects the reality of which it would be difficult to credit, were it not attested by woful experience and daily observation. Circulation, too, is independent of the will, its organs being excited sufficiently to ensure the regular continuance of their actions, by the fluid which digestion supplies and which respiration vitalizes. Yet here, also, though nature has provided for the regularity of this function, and rendered it independent of direct interference, man contrives indirectly to disturb it by over-excitement through excess of nutritive matter and abuse of various stimulants. So far is the body ensured against the neglect or imprudence of the individual, that what is absolutely necessary for existence is carried on by the mere incitement of appetite, and through actions in which the will has no share. But though mere existence is thus capable of being maintained for a while with little effort, voluntary exertion is still necessary for giving even to these independent functions the activity necessary for healthful vigour. Unless exercise, in its ordinary sense, be taken, neither respiration nor circulation can fully accomplish the purposes which they are intended to serve ; and proportional decline of health and strength must ever ensue. Exercise conduces to healthful digestion, perfect respiration, and efficient circulation. Neglect of exercise weakens the stomach, inducing changes in the digestive processes unfavourable to the formation of healthful chyle ; it tends to reduce the capacity of the chest, and thus to render the respiratory process less effective ; and it diminishes the actions of the heart and arteries to the extent of suppressing some of the most important functions to which they are subservient, namely, those which take place in the capillary system. For propelling blood duly into *all* the capillary vessels, a certain portion of exercise is indispensable. If this be not taken, some or other of those vessels will be inadequately supplied ; and in proportion must their functions decline, while the blood which ought to pervade them is thrown back on the larger trunks, overloading and oppressing the general system.

Life subsists through a series of motions, and all these should be maintained in regular and ade-

quate exercise. If any become suspended, or decline beneath the activity necessary for the due performance of their respective functions, the organs shrink, and more or less impression on the general health ensues, according to the importance of the parts consigned to quiescence. If there be total suspension, the organ then undergoes changes wholly subversive of its character and functions. A vessel which ceases to convey its proper fluid becomes soon changed into a solid cord. Muscular fibres, if consigned to inactivity, waste progressively, with proportional loss of power, until at length they approach the state of simple membrane. The laws of muscular action require that the muscle, in order to retain even its natural structure, must be continued in the adequate exercise of its natural functions, else it declines both in volume and power, and all the functions to which its actions are subservient, become impeded in consequence.

The foregoing sketch, though brief and imperfect, may suffice to show what is meant by referring to the natural laws. The subject, however, is not yet sufficiently matured for an elementary exposition of the whole of them, and at all events the writer of the present article is unprepared to attempt it. Whatever remain, therefore, applicable to the present purpose, must be left for the occasions which in the course of this essay may call for their introduction.

In pursuing the subject of physical education, the period of life to which it applies may be divided into the consecutive stages of Infancy, Childhood, Adolescence, and Puberty. The distinctions are sufficiently intelligible without assigning exact limits to each. To do so by a division of years would conduce but little to precision, for individuals differ so much, that similar ages do not necessarily indicate corresponding stages of development either in bodily or mental powers.

**INFANCY.**—The management of infants has been much improved in modern times, and many hurtful prejudices have been utterly extinguished. None, at least in this country, even of the most ignorant, deem it necessary at the present day to swathe the infant's body so as to deprive its limbs and head of all free motion, as was long the universal practice, and in some countries, even of Europe, continues to be so. The infant is now suffered to enjoy the unrestrained exercise of its muscular energies so far as its limited powers of exerting them permit. This was a great emancipation, and conducive not only to physical but also to moral improvement. The exercise of every natural power is accompanied with pleasurable feeling, and, without resorting to metaphysical refinements, it may, from a close analogy, be averred that the infant is sensible of pleasure from the free exercise of its motive powers, and suffers pain from their restriction. These sensations excite moral emotions, and without any great stretch of imagination, it is possible to detect the dawning of an irritable temper at a period of life when a moral feeling is scarcely supposed to exist, and to trace its development to irritations which enlightened caution might prevent. Even at this early period the moral laws are not to be disregarded. These laws pronounce that moral

feelings no less than the physical powers acquire force by exercise, and that the surest way of weakening those which, when tending to excess, lead to evil, is to consign them as much as possible to quiescence. Great care is therefore necessary not to arouse angry passions, and especially in infancy, when the other moral feelings, and the intellectual powers by which they are in later years controllable, are too imperfectly developed to be of avail. The principle is applicable to every period of life, and the interesting stage now under discussion should have the full benefit of it.

The present occasion does not call for minute details of the management of infants, which are so familiarly known and so much under the guidance of competent advisers, being for the most part regulated by enlightened medical attendants, that a few general remarks may here suffice. They may be comprised under the heads of clothing, food, state of bowels, air, temperature, cleanliness, exercise, moral discipline, and habits.

**Clothing.**—The clothing of infants should be soft in texture, so as not to irritate their tender skin. It should be made so as to give free play to all the limbs, no part being subjected to constriction or undue pressure, and should also be so simple as to admit of being quickly adjusted. The process of being dressed is irksome to most infants, causing them to cry, and exciting as much mental irritation as they are capable of feeling. It should, therefore, be rendered as brief as is compatible with the ablutions required, and with the necessary adaptation of the garments to their several purposes. By a very little ingenuity they may be so constructed as to be put on and removed with little delay. It would be well if pins could be wholly dispensed with, their use being hazardous through the carelessness and stupidity of nurses, and even through the ordinary movements of the infant itself. Soft tapes, loops, and buttons, hooks and eyes, or other such fastenings, might be beneficially substituted.

**Food.**—That the infant should derive its earliest sustenance from the mother's breast was so obviously designed by nature, that the abstract propriety of mothers suckling their offspring admits of no dispute. The question, however, whether all mothers should discharge this duty is not thus determined, the condition of the mother and her capability of performing it requiring to be taken into account, as well as the wants of the child. When a mother is young, healthy, and sufficiently robust, it is her bounden duty, as it ought to be her dearest pleasure, to foster in her bosom the being which she has brought into existence, and to nourish it with the food expressly provided by nature for its use. Every consideration, both physical and moral, pleads for this exercise of maternal function. By it the bodily health of both mother and child is promoted, while it excites in both the purest emotions of the heart.

All mothers, however, are not capable of performing this duty; and, unfortunately, among the higher and middle classes of society, a considerable portion, through errors of physical education, and the debilitating effects of various pernicious practices proceeding from fashion, luxury, and dissipation, are incapacitated for undertaking it. Thus error perpetuates itself, and in its natural

consequences comes to act in a circle. The dissipated mother neglects her child, and this child, if a female, commences life under disadvantages which, by weakening her frame, tend to unfit her for eventually acting as a mother. Extreme delicacy of constitution, diseased condition of the frame, defective secretion of milk, may forbid the mother to suckle her child. Unless she can perform the duty with safety to herself and benefit to her infant, she ought not to attempt it. In this case a young and healthy wet-nurse is the best substitute. But even this resource is not always attainable, and then it is consolatory to reflect that children may be reared without material prejudice to health, by what is termed feeding by hand, though extreme care is requisite to make the substitution effectual. In this case the process of nature should be emulated as far as possible, and food should be imbibed by suction from a nursing-bottle, rather than swallowed from a spoon. Much injury results from giving infants food too gross for their digestive powers. If nursing by hand, as it is termed, be resorted to, the food, for the early months at least, should approach as nearly as possible to human milk. Milk and water, with a little sugar, is quite enough for the first two months. After which some farinaceous matter may be combined. Thick gruel, panada, biscuit-food, and such matters, are much too solid, at least in very early infancy. They overload the stomach, causing indigestion, flatulency, and griping. These create a necessity for purgative medicines and carminatives, which again weaken digestion, and by the unnatural irritation perpetuate the evils which render them necessary. Thus many infants are kept in a continual round of repletion, indigestion, and purging, with the administration of cordials and narcotics, who, if their diet were in quantity and quality suited to their digestive powers, would need no aid from physic or physicians.

The frequency with which medical aid is required for infants under gastric and intestinal disturbance, and the numerous infantile maladies which spring from this source, are sufficient proof that their ordinary diet is not as rational as it might be rendered. From errors of diet are the digestive functions of infants chiefly, if not solely, liable to be impaired, and, when these become so, correction of diet, rather than the exhibition of drugs, should be relied on for remedying the evil. We are far from inculcating that on such occasions medical advice should not be resorted to; on the contrary, our persuasion is, that, when such disturbance arises, medical counsel is absolutely necessary, as the medical adviser is more likely to see the real nature of the evil, and adopt rational means for its correction, than they whose injudicious proceedings occasioned it. But we would strenuously advise the medical attendant to be sparing of his drugs, unless he see adequate cause for exhibiting them. We are well aware that, even in infancy, the bowels may become loaded, and their lining membrane coated with redundant mucus, and that purges, even of calomel and antimony, with rhubarb or scammony, may be required to cleanse them, and restore healthy secretion. But such remedies should not be prescribed on every trivial occasion, and at all events a succession of such

drastic purges can very rarely be needed. The stools, if rightly understood, will furnish a sufficiently certain guide. If there be evidence of redundant and vitiated secretion, and if the removal of this by purgatives relieve pain and restore tranquil feelings, no doubt can attach to the means by which these effects are obtained. But it sometimes happens that some tinge in the feces, some incidental pain, misleads the practitioner, inducing him to believe that more purging is needed, when the prevailing distress may be owing to the irritation caused by the purgatives already too freely administered. In this case he will do well to pause, and, by abstaining from interference, suffer the bowels to recover the tranquillity which his remedies serve to disturb. It is a valuable part of medical science to know when to resolve on doing nothing, and an excellent result of moral courage to dare to act on that resolution. On such occasions it is not true that medical skill is at fault or in abeyance. It only evinces the sagacity to perceive that nature is competent to her own work, and that she ought not to be interrupted in completing it.

In judging of the intestinal secretions of infants, there is a source of fallacy which deserves to be noticed. Mucus accumulates on the lining membrane of the stomach and bowels, and becomes morbid, inducing disease. The irritation of purgatives, too freely given, will also cause an increased secretion of mucus manifested in the stools. The matters discharged, however, are very different in their nature, and can hardly deceive an experienced eye. In the former case, the mucus is opaque, dense, ropy, or membranous; in the latter, it is limpid and fluid. Purgatives relieve the former condition; they exasperate the latter.

Infants naturally have free bowels, and, if properly fed, they need no medicine. Even in purging off the meconium, art is often superfluously resorted to, or at least prematurely employed. The first milk of the mother's breast is the natural purge, and oftentimes even this is not required. A too early exhibition of castor-oil, as is very generally practised, is unwise. A little manna is less irritating, and will in general suffice. Simple suppositories were formerly much in use, and perhaps they have been too much laid aside. When distress, however, arises from distension or flatulency under retention of the meconium, some aperient is needed, and, for certainty of effect, castor-oil is perhaps most to be relied on. With respect to the general management of the bowels of infants, the principle is that they should be kept free, and by the mildest and least irritating means. This is all that health requires. It may be finally remarked, however, that no course of proceeding can be more prejudicial than, having first overloaded the stomach and then administered purgatives, followed by carminatives and narcotics, to return to the dietetic errors which created the necessity for all this discipline.

**Air.**—It is of importance that children should breathe a pure atmosphere. During the day this is in general sufficiently attended to; but at night they are very apt to be placed under circumstances unfavourable to a free circulation of the air around them. Apprehension of cold causes them to be then more closely enveloped with clothing, esp

cially about the head; curtains are drawn in order to exclude cold air; nay, through extreme care, a thin covering is not unfrequently thrown over the face of a sleeping infant, confining the respired air, and impeding the access of fresh air required. All these practices are bad, and ought to be avoided. The head should not be muffled, curtains are objectionable, and the face should not be covered during sleep. Pure air is needed, and a supply of this should be ensured without giving way to undue apprehension of cold, of which the danger is very slight, unless great imprudence be practised. Infants should be guarded from cold, but much heat is prejudicial. On this as well as on several other accounts, the child should not lie in the bed with the nurse. After having sucked, it should be placed in a cradle with just so much covering as is necessary for preserving the natural temperature.

**Cleanliness.**—Cleanliness is essential to the health of infants, the functions of the skin being of high importance, and requiring to be kept in due activity. The body should be washed all over once a day at least, and impurities should never be suffered to remain for any time in contact with the skin. At first the water used should be tepid, but after a few months the temperature should be gradually lowered, until cold be employed, unless there be such extreme delicacy and deficient re-action as to render this hazardous. Children bear well the transient application of cold, which is in general succeeded by a genial glow, both refreshing and invigorating. Many weakly children are renovated in health and strength by means of a daily plunge in a cold bath.

**Exercise.**—Infants, for the first month or two, sleep so much that there can be no exercise, save that of being carried about in the nurse's arms. After this time it is advisable to suffer them to exercise their limbs freely, by laying them frequently on a bed, sofa, or carpet, and allowing them to roll and kick at their good pleasure. The delight which this affords evinces how grateful such freedom is to their animal feelings.

There is one very common mode of exercising infants, which, we think, deserves particular notice—we mean the practice of *hoisting* or raising them aloft in the air. This practice is of such venerable antiquity, and so universal, that it would be vain to impugn it. The pleasure, too, which most children evince under it, seems to show that it cannot be so objectionable as a cursory observer would be disposed to consider. Still there are hazards which ought not to be wholly overlooked. The risk of accident is one of some amount: children have slipped from the hands, and sustained serious injury. Some people are so energetic as to throw up children and catch them in descending. This rashness there can be no hesitation in reprobating, for however confident the person may be of not missing hold, there must ever be risk of injury from the concussion suffered in the descent, and even from the firmness of grasp necessary for recovering and maintaining the hold. The motion of the body, too, has a direct tendency to induce vertigo; and when the liability of the infant brain to congestion and its consequences is considered, when the frequency

of hydrocephalus in infants is borne in mind, an exercise which impels blood to the brain will not be regarded as wholly insignificant. There is one more objection which seems not to have attracted attention. The hold taken of a child in the act of hoisting it is by the hand grasping the chest. The fingers and thumb placed on each side of the sternum, compress the ribs, and any one with the hand so placed will at once perceive that if the pressure were strong, and the resistance from the elasticity of the ribs weak, the impression on the chest resulting would correspond exactly with the deformity named *chicken-breast*. That any force is ever used capable of inducing speedily such a change is in the highest degree improbable; but that reiterated pressure of this kind, however slight, would in a weakly child have power to impress and distort the chest, few, we imagine, will doubt.

Rocking was formerly in almost universal use with infants, though not meant precisely as exercise. Every cradle had its rocker, by means of which it was put in vibratory motion whenever the infant was to be set asleep. The expedient answered its purpose; but the propriety of inducing sleep by such means is very questionable, or rather must be utterly disallowed. Sleep here ensues because the motion promotes a congestive state of the vessels of the brain inducing a degree of vertigo. For the reasons already assigned when discussing the exercise of hoisting, this cannot be salutary, and must be scarcely safe in the delicate brains of infants.

**Moral Management.**—To notice the moral discipline of infancy may excite a smile; and yet it is a subject of no slight moment. From the hour of birth the infant is a moral being, and subject to the moral laws; and it is the duty of those who are responsible for its culture to see that these laws be not infringed. Bodily health, too, being more or less affected by mental excitement, a treatise on physical education would be incomplete if this source of disturbance were disregarded. Infants possess several propensities and passions of great activity; and as neither the countervailing sentiments, nor the intellectual powers by which they are to be controlled in after-life, are at this age equally developed, it is the more incumbent on those who govern them to regulate, on sound principles, the dispositions which they display. Good dispositions are capable of being cultivated, and evil of being restrained, even in the cradle. But they who undertake the task should look well after the government of their own minds; for if in pursuing it they yield to the impulse of feelings, unrestrained by the higher sentiments and unguided by the intellect, their measures will be ill adapted to the ends desired, and little likely to attain them. An irritable nurse is unfit for the care of a fretful child. The fretfulness may be owing partly to natural disposition; it often arises from impaired health, or from slight sufferings occasioned by some injudicious management. Rendered uneasy by overloaded bowels, constriction from the clothing, misplaced pins, or other source of disquietude, the infant has no resource but to cry; and if the cause of distress be not removed, habitual fretfulness and irritability of temper may become established. In a child of

natural good temper, when the distress is relieved, calmness returns; but if the temper be naturally irritable, this becomes aroused by the pains endured, and especially if under its sufferings the child be harshly or unkindly treated: so that even when the bodily distress ceases, equanimity is not restored. Children cry from pain; they cry also from passion; and no tones can be more distinct than those which express the respective feelings. The one should be promptly quieted by removing the cause of pain; the other is less speedily corrigible, requiring both time and a system of sound moral discipline, to prevent habits of irritability acquiring strength by reiterated excitement. When the natural temper is irritable, causes of irritation should be carefully avoided; the irritability should be calmly but steadily repressed; other faculties of the mind, too, should be called forth, as indirectly suspending the exercise of the irritable feelings; and according as the mental powers become progressively developed, the higher sentiments and intellectual faculties should be so cultivated as to ensure them that predominance over the animal propensities which the Creator has allotted to them, and on the maintenance of which all virtue and happiness depend. To exercise this controlling power in due time is the greatest good which the infant can experience; it lays the foundation of all moral improvement, and cannot be too early commenced. No error can be more pernicious in its consequences than to be reckless of exciting the passions of children, without considering how they are to be allayed. Some have been so misguided as wantonly to excite such passions in order to habituate the parties to self-control; but this error is so mischievous, and so irreconcilable with all sound principle, that it must be of rare occurrence. Even carelessness, however, in this respect is inexcusable; and no child should be subjected to any irritation that can be avoided. Frequent excitement will, in the naturally irritable, confirm ill temper, while it will endanger the establishment of it, even in those who are naturally more calm. Irritability of temper in children should be regarded rather in the light of a disease to be remedied, than of a fault to be punished. They are as nature made them, and no more accountable for irritability of temper than for a weak digestion or other bodily infirmity. The possession of an irritable temper is a misfortune rather than a fault, and the being so unhappily circumstanced merits pity rather than reproof. All the assistance which kindness and sympathy can render should be given in support of the struggles which such a being has to maintain within his own breast. Imperturbable calmness is required in the government of children, who readily distinguish whether reproof or punishment proceed from excited passion, or are resorted to solely for their correction or improvement. This discussion, however, must terminate here. Enough has been said to mark the close connection that subsists between moral discipline and physical welfare. Tranquility of mind is essential to good health, and the government of the passions is important towards attaining the ends of physical education.

In rearing children it is necessary to bear in mind the force of habit, by which, in many parts

of the animal economy, regularity is maintained with a precision which the dictates of reason could never command. Many of the bodily functions are signally under its influence; and on the principle that activity gives vigour, while quiescence leads to abatement of energy, much of moral discipline may be founded on the formation of habits during those early years when the self-controlling powers of the individual are yet but imperfectly developed. In respect of food, of sleep, of the alvine discharges, a disposition to periodic recurrence is clearly discernible; and by attending to it, regularity of the respective functions may be sensibly promoted. Fixed periods for taking food are desirable, and they should be frequent. It is unwise to load the stomach with fresh food until the previous meal has been digested and passed onward to the intestines. From this error the gastric and intestinal irritations of infancy oftentimes proceed. Regular habits of evacuating the bowels, if duly established, have much effect in superseding the use of medicine. So prone are the bowels to make at certain periods efforts for their own relief, that if from any cause the periodic impulse be resisted, the effort ceases, and is not again actively renewed until the next revolving period arrives; accumulations, productive both of inconvenience and injury, going on during the interval. It seems needless to pursue further the consideration of infancy. What has been said furnishes sufficient guidance for conducting the ordinary management of health, and for guarding against the errors to which this stage of life is exposed. So many of the principles inculcated in the foregoing inquiry apply to the next stage, or that of childhood, that this may be more briefly discussed. [See a Treatise on the Physiological and Moral Treatment of Infancy, by A. Combe, M. D., Amer. edit. by Dr. J. Bell: Philad. 1840.]

**CHILDHOOD.**—In considering the stage of childhood, we shall, for the sake of method, pursue the same arrangement that was followed in treating of infancy, without deeming it necessary, however, to dwell more circumstantially on any point than its merits may specially require.

The clothing of childhood should possess the same properties as that of infancy. It should afford due warmth, be of such materials as do not irritate the skin, and so made as to occasion no unnatural constriction.

On the feeding of children their health is much dependent; and in this respect injury is often done from regulating their diet according to some preconceived system founded on partial experience or imperfect observation. Children, to support their natural growth, require ample sustenance, and this admitted truth is with many a sufficient reason for overloading their stomachs, and with food of too nutritious a kind. Others again, from having seen healthy children reared on a low diet, and, also from having occasionally witnessed disease brought on by excess of animal food, unaware, too, of the hazard of generalising from insufficient facts, hastily conclude that low diet is wholesome, and animal food prejudicial. No exclusive system can in this respect be right, nor can any precise rule of diet be possibly laid down, as this requires to be adapted in every case to the particular constitution concerned. It has

been already shown that a mixed diet of animal and vegetable food is that which nature has designed for human beings; their organization being fitted for its use. The period, too, when animal food may begin to be used seems also indicated by nature, and some portion of it seems fairly admissible as soon as teeth appear sufficient to masticate it. These, however, are but general truths, which require continually to be modified in their application by special circumstances. The constitution of the child, and the effects of particular diets, will in general indicate sufficiently how it may be best sustained. If of a sound constitution, free from fever or evidences of plethora, with healthy bowels, a cool skin and clear tongue, the diet may be liberal, and some animal food may be conjoined. It is not wise to stint the growth of children by a too low diet, for, however it may for a while appear to agree, it induces a state of body deficient in vigour and unfit for maintaining full health. Children so reared are prone to scrofula, and to several other diseases marked by impaired energy of frame. Yet neither should children be pampered; for this leads to evils no less formidable, though of a different character. Large meals oppress the stomach, cause indigestion, and by overloading the bowels, obstruct one of the most important excretions. Too much animal food supplies blood in excess, begetting a proneness to fever and inflammation; and every one is aware how large a portion of the diseases of children is thus characterised. So long as the general health is unimpaired, the body and mind active, and no evidence present to mark excess of nutriment, that food may be allowed which natural appetite calls for, and which appears to yield adequate nutrition; and in such case a mixed diet of animal and vegetable food will be found the best for this purpose. But if languor at any time ensues, and febrile indications become manifested,—if the pulse become frequent, the skin hotter than natural, the tongue white and furred, the bowels irregular,—then, though these several symptoms should be only in slight degree, and unattended with any specific derangement amounting to what is considered disease, not only should the diet be lowered, and its animal part for a time withdrawn, but measures should be taken to correct the state of repletion which has been suffered to arise. For some time after its removal, too, care should be taken to keep the diet under that which occasioned the constitutional disturbance.

These observations apply to children of sound constitutions and robust health, and attention to them may be the means of averting much disease. In such the plethora so induced is positive; that is, the blood generated exceeds what the constitution in its most healthful state could need or dispose of. But there is another, and a numerous class of constitutions in the management of which further principles are needed. These are by nature less robust, and, possessing less powers of resisting slight influences, their health becomes more or less impaired. The weakness induced disinclines to exercise; and thus a further source of derangement is superadded. Under these circumstances, the nutritive matter introduced into the system, though not exceeding what the same constitution in a state of health and vigour would

require, is redundant under its altered condition. The enfeebled powers cannot dispose of it; and hence arises a state of relative plethora, producing all the evils of the positive, while, from the partial weaknesses that co-exist, it is capable of inflicting still more injury on the frame. It is the *plethora ad vires* of the older writers; and the febrile state which it induces is, like that of the positive plethora, relieviable by evacuations and abstinence. But for the restoration of perfect health, something more is needed than merely getting rid of the febrile excitement. Suitable treatment will abate the plethora, remove the fever, and correct the incidental derangements, so as to bring back the constitution to the point from which the occurrence of relative plethora had caused it to deviate, and increased caution in diet may prevent the plethora recurring. But by adhering to this caution, the food required for full health may be withheld, and feebleness of habit becomes established. In this state, while it is necessary to limit the diet so long as evidences of renewed plethora are prone to occur, the necessity of improving the habit, so as to enable it to bear more adequate nutrition, should be borne in mind. Moderating by cautious depletion the circulation when overcharged, preserving a free state of excretions, increasing the exercise, restoring tone by cold ablation or the shower-bath, with other alterations contributory to the same end, will, if judiciously applied and steadily persevered in, restore many such constitutions to a state of vigour capable of bearing the diet of full health, and exempting the parties from manifold diseases to which they would otherwise be exposed. It will be perceived that the measures here enjoined are partly remedial, partly restorative; and it is of the first importance that the right order of their employment be not reversed. If, while the remedial measures are needed, the fear of debility or other prejudice lead to the premature use of restorative means, the whole coorrective process is disturbed and rendered impracticable, and disease more or less formidable is sure to result.

Regulation of the bowels is one of the most important attentions by which the health of childhood is preserved. Children of sound health, who are properly fed and have sufficient exercise, will rarely need aperient physic. Nature is fully equal to her own work, and if not obstructed will effectually perform it. Still the bowels of children will occasionally get deranged, and their incidental irregularities cannot be too soon rectified; for, independently of the local distress which a disordered state of bowels occasions, so long as this continues, a most important function of health is suspended, and part of its duties becomes transferred to other organs unfitted for discharging them. Various irritations, too, resulting from nervous sympathy, ensue. To restore a healthy state of bowels whenever these become deranged, is an important part of the physical management of childhood. For this, simple means should be preferred; but if they fail to re-establish regular evacuations with healthy secretions, more active remedies must then be resorted to, the direction of which belongs not to this place.

Children should breathe a pure atmosphere both by day and night. By day they should be much

in the open air, and allowed to exercise their limbs freely, short of fatigue. Long walks are objectionable, and a single over-exertion of this kind is capable of doing permanent injury. In treating of exercise we wish to give one caution applicable to that period when the child first attempts to walk. Its early efforts are viewed with so much delight that they are apt to be encouraged and prolonged without regard to the mischief which they may occasion. The bones of infants have little resistance, and time is required ere those of the legs are capable of sustaining the weight of the body. If prematurely subjected to it, they actually bend and become curved; and many an inconsiderate mother has to mourn over the deformity which she has herself created. In the upper classes of society this result perhaps is not frequent. It occurs chiefly to young mothers who have weakly children, and for obvious reasons the first child is most exposed to it. Among the poor it is very common, though their indiscretion springs from somewhat different feelings. With them it is less the indulgence of maternal emotions, gratified by the child's exhibition of strength, that leads to this distortion, than the necessity of confiding very young children to the care of others but a few years older. This distortion, if timely noticed, is capable of correction, even after sensible curvature has taken place. Such children are in general feeble; and renovation of strength with the regular action of the several muscles of the limb may counteract the injury sustained, and cause the deformity to disappear. But to produce this effect the original cause of distortion must be sedulously avoided, until firmness of bone and strength of muscle remove all hazard of perpetuating or renewing the evil. In addition to other means of establishing the necessary vigour of frame in such cases, a daily plunge in a cold bath is of signal efficacy.

It is hardly necessary to enter further into the physical discipline of childhood; nor is it required in this stage of existence to make any distinction between males and females. Happily for the latter, they are, during childhood at least, strangers to those restrictions and injurious practices from which in later years they are doomed to suffer so severely. From this period on to puberty a marked difference prevails in the management of boys and girls, greatly to the prejudice of the latter; and it is to the errors thus committed, and the calamitous evils which they inflict, that attention will be chiefly directed in the following pages.

**ADOLESCENCE.**—Boys, though oftentimes too much confined by the prevailing systems of school discipline, have on the whole considerable liberty, and they avail themselves of it so as to exert freely and actively their muscular energies. By such exercise their growth is promoted, their vigour improved, their health maintained, and a robustness of frame acquired exceeding that of girls to a degree far beyond what mere difference of sex would account for. Very different is the fate of female childhood as it passes onwards to adolescence. When this latter stage is approached, the trammels of error, prejudice, and false system begin to be imposed, restraining the free exercise of body and mind, and conforming both, not to what reason and right feelings enjoin, but to what

fashion and vanity dictate. The body, instead of being suffered to attain its just proportions uninfluenced by interference of art, is to be trained into those forms which the caprice of the day admires, however unnatural, or however unbecoming in the eye of unvitiated taste. The limbs, formed for activity, and requiring free exercise for the development of their structure and the maintenance of their powers, as well as for the preservation of general health, are to be restricted to those movements to which a fancied gracefulness attaches, even though the best powers both of body and mind wither under the blighting influence of the vicious system. The mind fares no better; for instead of the cultivation of those intellectual powers and moral feelings which conduce to utility, happiness, and virtue, the best years of life are wasted on vain accomplishments, which, even when attained, are too dearly purchased, yielding but a very inadequate recompense for the time and toil bestowed on them, and which in a large proportion of instances, from being forced against nature, and without the talents that would justify such assiduous cultivation, are never acquired to the extent of answering a single good purpose, being sure to be abandoned as soon as the parties become free agents, and released from the control of their unrelenting taskmasters. Each of these subjects will require to be considered more in detail; and above all, attention must be forcibly drawn to those horrible ravages in female health that result from the visceral lesions which the tyranny of fashion occasions. To any one impressed with the reality and extent of the evils here deprecated, it is difficult to think or write on them with perfect calmness. We shall endeavour as much as possible to confine ourselves to a plain exposition of the evils deplored, and of these we shall adduce only such evidences as admit of unequivocal demonstration.

Of boys it is unnecessary to say much, as the principles already inculcated apply to them equally as to infants and children. To them the advance from childhood brings but greater freedom; and if the confinement of school exceed what sound reason and the philosophy of nature would sanction, they redeem the mischief by the active unrestrained gambols in which they indulge when school-hours are over. They pass much time in the open air, exercise freely, take food with appetite, and digest it thoroughly; whence the stomach and bowels are seldom disordered, and their sleep is sound and refreshing. Their clothes, too, make no injurious pressure; all their muscles are at liberty to act, and the free exercise of these promotes both their growth and activity, ensuring thus the regularity and efficiency of the several functions to which these muscles are subservient.

With girls, the ordinary modes of proceeding are much less healthful. It is not that their health is less an object of regard, or less carefully tended, but other considerations than those of health obtain an undue share of attention, and various practices subversive of health are pursued in ignorance of the extensive mischiefs to which they lead. After childhood, education formally commences, and from this period certain objects of maternal solicitude are pursued with a zeal and earnestness which, if well directed, would be

worthy of all praise. As it is, that of good intentions can only be awarded; for the tendency of much that occurs at the periods of life now under consideration is to render valueless all the cares lavished, by breaking down the constitution.

The first error is that of restraining the free motions of the body and limbs, so natural at this period of life, and in which the young of both sexes so much delight. The young lady is now to cultivate manners, to practise a certain demureness supposed to be becoming, to attend to her carriage, keeping her head erect, and her shoulders drawn back; and if from inability to continue the muscular efforts necessary for this end, she fail to do what nature does not empower her to accomplish, negligence or obstinacy is imputed, reproach is cast, which, being felt as unjust, irritates the moral feelings; and thus a slight error in physical discipline becomes a fruitful source not only of bodily injury but of moral depravation. It is a well-established fact with respect to muscular energy, that the contractions of muscular fibres on which their actions depend, require intervals of relaxation; that, if the contractions be prolonged without this relief, they in a certain time fail, so that no effort of the will can continue them. In other words, the muscles tire, and an interval of repose is necessary to fit them for renewed effort. This is familiarly instanced by the experiment of holding the arm extended, when, even though no weight be held in the hand, the continued muscular action required for maintaining this position cannot be sustained for many minutes. If this be true of the firm and robust muscles of adults, how much more forcibly does the principle apply to the tender and immature muscles of early life! To preserve a good carriage, to keep the head and shoulders continually in that position which the dancing-master approves, require considerable muscular powers, such as no girl can exercise without long, painful, and injurious training, nor even by this, unless other measures to be hereafter noticed, be resorted to in aid of her direct endeavours. We would not here be understood as undervaluing a good carriage, which is not only pleasing to the eye, but is, when natural, absolutely conducive itself to health, as resulting from that relative position of the several parts connected exteriorly with the chest, which allows greatest freedom to the internal organs. To ensure a good carriage, the only rational way is to give the necessary power, especially in the muscles chiefly concerned; and this is to be done, not by wearying those muscles by continual and unrelieved exertion, but by invigorating the frame generally, and more especially by strengthening the particular muscles through varied exercise alternated with due repose. Attention to general health, suitable diet, regular bowels, moderate but regular exercise, not of particular muscles only, but of the whole frame, cold bathing when needed, and other such measures, will maintain a good carriage by giving that power which the more direct means so generally practised served but to exhaust. All this may appear trivial and of slight importance, yet the principle inculcated is far from being so; and it applies to this early stage of life as forcibly as to those more advanced. Nay, more so; it is at this stage that its observance is of greatest mo-

ment; for if it be here disregarded, effects may result, which, though not immediately obvious, are capable of laying the foundation of evils that cannot afterwards be redeemed. It is possible that the principle might be more clearly illustrated, more forcibly inculcated in connection with those later periods of life when the consequences of disregarding it are more prominent; but we prefer dwelling on it in its earliest and simplest applications, as a clear conception of these will materially assist in unravelling and comprehending the more complex conditions which are hereafter to be noticed. The evils produced by errors in physical education oftentimes beget actual disease, and the nature of this will ever be more intelligible in proportion as we ascend to the causes which primarily induce it. It has been shown that direct endeavours to enforce what is called a good carriage necessarily fail of their effect, and that instead of strengthening they enfeeble the muscular powers necessary for maintaining it. This fact soon becomes perceptible; weakness is noticed, and instead of correcting this by the only rational mode, that of invigorating the weakened muscles, mechanical aid is called in to support them, and laced waistcoats are resorted to. These undoubtedly give support,—nay, they may be so used as almost wholly to supersede the muscular efforts, with the advantage of not tiring, however long or continuously employed. Improvement of carriage is manifested, the child is sensible of relief from a painful exertion, the mother is pleased with the success of her management, and this success appears to superficial observation fully to confirm the judgment which superintends it. In the present ignorance that prevails on all points of animal physiology, it would be quite impossible to convince any mother so impressed that she was doing otherwise than ministering to her child's welfare. Yet what are the consequences to which her measures tend, and which such measures are daily and hourly producing? It has been shown in the foregoing pages, when noticing the organic laws, that a muscle consigned to inactivity not only loses power, but becomes attenuated and wasted, its nutrition failing from want of that energy which due exercise alone can confer. The fact is notorious, the principle unquestionable, although its application to the case under consideration has been little heeded. The muscles of the back and chest, restrained in their natural and healthful exercise by the waistcoats called in to aid them, and more signally in after-life by the tightly-laced stays or corsets, become attenuated, and still further enfeebled, until at length they are wholly dependent on the mechanical aid, being quite incapable of dispensing with it for any continuance.

At first, laced waistcoats are used rather for the convenience of suspending other parts of the dress than with any view of giving support to weak muscles, or of influencing the shape; and confined to such use they would be perfectly harmless. In time, when weakness becomes inferred, not from any evidences of actual debility, but merely from the girl's not being able to maintain the unnatural and constrained posture which fashion and false taste enjoin, the advantage of compressing the chest by means of the waistcoat, so as to give sup-

port to the muscles of the back, becomes discovered, and the mechanical power supplied by the lace affords but too effective means of accomplishing this compression. The effect pleases the mother, promoting, as it does, her dearly-prized object—a good carriage; it is endured by the girl as the lesser of two evils, for though at first irksome, it releases her from the pain of endeavours which she has not power to continue to the extent required. As years advance, various causes combine to render this practice more inveterate and more pernicious; and still the potent instrument, the lace, extends its ready and effectual aid. The extent to which this practice prevails, and the degree to which it is carried, are too notorious to need being dwelt on. Extreme cases we wish not to state, lest they should appear exaggerations; but daily observation displays to all who walk our streets, and still more signally to those who frequent our assemblies of fashion, the many victims who, through tight lacing, sacrifice health, and too often life, at the shrine of empty vanity.

It is time now to scrutinize the further injuries which this unnatural practice inflicts. The first evil is already suffered in the dorsal weakness occasioned by mechanical support having superseded muscular energy. The muscles are become enfeebled and attenuated; their physical condition unfits them now for doing that for which nature designed them; the stays are become indispensable, and, so strong is the faith in their necessity, that a proposition to discard them would be accounted monstrous. A conception that they could be laid aside would be regarded as quite too improbable to be for a moment entertained. But now a taper waist becomes an object of ambition, and the stays are to be laced more closely. This is still done gradually, and, at first, imperceptibly to the parties. The effect, however, though slow, is sure, and the powers of endurance thus exercised come in time to bear almost unconsciously what, if suddenly or quickly attempted, no heroism could possibly sustain.

The derangements to which this increased pressure gives rise must now be considered. The first is the obvious impediment to the motions of the ribs which this constriction of the chest occasions. For perfect respiration these motions should be free and unrestrained, and, as has been already noticed, perfect respiration is necessary to those changes in the blood which fit it for nutrition and the other purposes of the animal frame. In proportion as respiration is impeded, is the blood imperfectly vitalized; and in the same ratio are the nutrient and other functions dependent on the blood inadequately performed. Here, then, is one source of debility which affects the whole frame, reducing every part below the standard of healthful vigour. According, also, as each inspiration of air becomes less full, the wants of the system require, as a compensation, increased frequency; and thus quickened respiration commences, disturbing the lungs, and creating in them a tendency to inflammatory action. The heart, too, becomes excited, the pulse accelerated, and palpitation is in time superadded. All these effects are capable of resulting from mere constriction of the chest; they become fearfully aggravated when, at a more advanced stage, as will be more fully shown in the

sequel, additional sources of irritation arise in flexure of the spine, and in derangements of the stomach, liver, and other organs subservient to digestion. The foregoing disturbances are formidable enough, and sufficiently destructive of health, yet they are not the only lesions which tight lacing induces. The pressure, which is chiefly made on the lower part of the chest, and to which this part most readily yields, extends its malign influence to the abdominal viscera also. By it the stomach and liver are compressed, and, in time, partially detrued from the concavity of the diaphragm, to the great disturbance of their functions; and being pressed downwards, too, these trespass on that space which the other abdominal viscera require, superinducing still further derangements. Thus, almost every function of the body becomes more or less depraved. Nothing could have prevented the source of all this mischief and misery from being fully detected and universally understood, but the slow and insidious process by which the aberration from sound principle effects its ravages; and on this account it is that we lay so much stress on the remoter evils when considering the primary errors, for it is only by tracing those to their source, and by connecting the several visceral lesions which ultimately take place with the incipient and apparently harmless errors which form the earlier links in the chain of causation, that any hope can be entertained of those evils being clearly understood or effectually rectified.

It must be seen that the same principles apply to every stage of this destructive system, and that, however insignificant the effects of the early waistcoats may appear when compared with those of the tight-laced corset, the same false principle is manifested throughout. The girl's waistcoat, if used otherwise than as a support for the other articles of dress, is improper. When tightened in order to support the back, instead of giving strength, it produces real weakness by the effect on the dorsal muscles already described; and when further straitened, so as to diminish the waist, it then commences that suicidal process which years of suffering and ill health are afterwards to complete.

But there are further evils yet to be noticed. The mere weakness of back, so often adverted to, becomes in its turn an aggravating cause of visceral lesion. The body cannot be always cased in tightly-laced stays; their pressure may be endured to any extent under the excitement of the evening display, but during the day some relaxation must take place. Under it, the muscles of the back, deprived of their accustomed support, and incapable of themselves to sustain the incumbent weight, yield, and the column of the spine bends, at first anteriorly, causing round shoulders and an arched back; but eventually inclines to one or other side, giving rise to the well-known and too frequently occurring state of lateral curvature. This last change most frequently commences in the sitting posture, such females being, through general debility, much disposed to sedentary habits. As soon as lateral curvature commences, the lungs and heart become still more disturbed; anhelation from slight exertion, short cough, and palpitation ensue; and at this time, chiefly in consequence of the pulmonary derangement, alarm

begins to be entertained, and the approach of phthisis apprehended. Medical aid is now sought, and as the more obvious malady is within the chest, and from the excitement which prevails presents an acute character, blood is drawn, and other means are resorted to suited for arresting inflammatory action. And to a certain extent the practice is necessary and right, for in this state there is often so much inflammation and congestion as fully to justify depletory treatment. Should the disease, however, be misconceived as primary inflammation of the thoracic contents, the relief, however signal at the time, must be transient, and, unless attention be given to those causes from which the perpetual derangements spring, enduring health has but little chance of being restored. Removal of the spinal flexure by using a recumbent instead of a sitting posture; alternating this with regular and proper exercise so as to call into renewed action the weakened and wasted muscles; invigorating these still further by cold sponging and stimulant frictions; and finally, renovating the general health by regulation of bowels, suitable diet, the cold shower-bath, and such tonic medicines as the constitution may need, are the appropriate and only effectual means by which this state of health can be permanently improved.

The views of spinal curvature here presented will be found more fully stated in a paper in the 5th volume of the Midland Medical and Surgical Reporter, to which the reader is referred.

We have already mentioned the injury which constriction of the chest inflicts on the liver and stomach. Either or both of these organs may under this disturbance display the ordinary evidences of local inflammation or congestion, and to these will apply all that has been already stated respecting the heart and lungs. The local inflammation or congestion may be real, and require depletion together with other active remedies, but they are liable to recur if the original disturbing causes be not rectified. They are sensibly aggravated as soon as the spine begins to yield, for according as the body bends forward, the lower ribs in connection with the sternum are forced inwards, increasing the pressure made on the liver and stomach, and further irritating these if already brought into a state of excitement.

But all the evils produced by the vicious course so long and so obstinately persisted in are not yet enumerated, an important train of consequences being yet to be noticed in the derangements of the uterine system. When the age of puberty is approached, the organization distinctive of sex becomes more fully developed, and in the female constitution certain changes take place the suppression or retardation of which is fraught with injury to health. Of these changes one of the most important, and that which is most liable to be effected by contingent influences, is menstruation. This function we mean here to consider only so far as it is prejudiced by the causes of ill health now under consideration. For menstruation to commence at the proper age and to continue regular and perfect, it is requisite that the whole frame be in a healthful state and every function adequately performed; consequently, the general depravation of habit lately described is eminently unfavourable to the establishment of this

natural process. There is also required a certain vigour of the constitution capable of propelling blood with sufficient energy into the capillary vessels, which vigour habits enfeebled in the way lately noticed do not possess. It is further necessary that the larger trunks leading to these capillaries be not overcharged, else congestion takes place, which further debilitates the overloaded vessels, rendering them still less capable of propelling their contents into the capillaries by the secreting functions of which they would be relieved. Yet this congestion is prevented by the impeded circulation arising from constriction of chest, and by the disturbance of the abdominal viscera lately explained. It is necessary, also, to take into account the various coincident efforts made by the constitution towards preparing for the signal revolution in the system which incipient menstruation indicates. When these efforts are defeated by menstruation not commencing at the proper period of life, much additional derangement of health ensues, and blood which ought to be disposed of by the uterine vessels becomes either congested in the surrounding tissues, or determined to other parts, so as to cause vicarious hemorrhages of various kinds. Thus the regularity and efficiency of the uterine functions, so essential to female health, become impeded and impaired by the injudicious measures which, when first resorted to in childhood, are little suspected of exerting any such influence.

Although so much has been attributed to constriction of chest in impairing general health, and occasioning special derangements, and assuredly not more than strict truth warrants, many other errors of physical education lend their aid to produce that feebleness of constitution and delicacy of health of which so many females are the victims. These shall be now considered under the same arrangement which was followed with respect to the earlier stages.

**Clothing.**—The clothing of young females is far from being what reason would sanction. It is oftentimes deficient in the necessary warmth, the materials being too slight to yield protection against the vicissitudes of a variable climate, and too much of the person being wholly exposed. Errors of this kind, however, are much more common and carried to much greater lengths at the period when *education*, in its usual sense, may be said to be completed; that is, when the young lady passes from the restraints of the school-room to the dissipations of fashionable life. As, however, this change usually takes place before the body has attained its full vigour, the following remarks on the dress and conduct of females, on first leaving school, belong properly to our subject. If the errors of dress are less signal in the attire worn by day, they reach their acme when the evening rout or midnight ball is to be attended. At these seasons the tightly-laced stays, exposed chest, and thin draperies, furnish a combination of influences, the continued effects of which no constitution could withstand; while to these is yet to be added that of respiring for hours a heated and vitiated atmosphere, and, after this, of passing, when relaxed and exhausted, into the cold currents of a frosty night air. So far from wondering that many suffer from these egregious imprudences, our

surprise should be that any escape; and instead of the inherent delicacy so often imputed to the constitution of females as explanatory of their peculiar ailments, we have ample proof, in their powers of resisting such noxious influences, that they possess conservative energies not inferior to those of the most robust male. Were men to be so laced, so imperfectly exercised, so inadequately clothed, so suffocated, so exposed, their superiority of bodily vigour would soon cease to have any existence.

Defect of clothing, though most signal in the chest and shoulders, is not confined to the upper part of the body. The feet require warmth, which subservience to fashion prevents. They cannot be compressed but at the cost of much suffering, some distortion, and the infliction of positive disease. Fashion also permits the legs to be covered with only the thinnest materials. Thus the capillary circulation of the feet, rendered sufficiently languid by the general weakness, becomes further impeded by the pressure of tight shoes, and the debilitating effects of cold. The crippled state, too, thus occasioned, is a further obstacle to efficient exercise, and so adds to the general debility.

**Food.**—The food of the young of both sexes, as indeed of every age, should be suited to the particular constitution. The general principles for regulating it have been already laid down. It should, for reasons already assigned, be rather nutritious than spare. The effects of casual repletion are less prejudicial, and more easily corrected than those of inanition; still the bounds of temperance should never be exceeded. There should be a due admixture of animal food, but wine and stimulants are needless and improper. It is to be hoped that no caution is needed at the present day against a practice, not unknown in the last century, of females inclining to corpulency reducing themselves by abuse of acids. The effect was produced by destroying the tone and injuring the structure of the digestive organs, and from the evils which resulted, we would fain hope that a practice so pernicious has been for ever abolished.

At the ages under consideration the state of the bowels requires to be attended to; and here again, girls suffer in a much greater degree than boys. The abdominal congestions to which their whole course of discipline subjects them, have no means of relief save the increase of alvine excretions. There is, therefore, even more to be carried off through this outlet than a state of health would supply. Yet from the general debility and deficient exercise the alvine discharges are very prone to be irregular and inadequate. Much disease would at this age be averted, and the conservative powers of the constitution would have a far better chance of being effectively exercised, if a regular and healthful state of bowels was maintained. For this there should be not only daily evacuation in sufficient quantity, but, what is still more important, the matter discharged should be of a healthy character. And here we would caution medical men against being misled by false delicacy so as to trust to reports, which are never to be relied on. Ocular inspection furnishes an indication of the highest value, both in exhibiting and withholding medicines; and so assured are we of its absolute necessity as a guide to medical judg-

ment, that we cannot understand how a medical practitioner can conscientiously perform his duty who disregards it. As it is the duty of the medical practitioner to avail himself of this source of information when attending patients under disease, it is equally so to point out to convalescents the importance of it to the maintenance of general health. Were the state of bowels in young females more attended to, ample evidence would be furnished of the necessity of some evacuant or corrective discipline, long before the accession of actual disease; and, what is of more importance, much accumulated and too often intractable disease might thus be altogether averted.

**Exercise.**—What has been already stated with respect to air and temperature in infancy and childhood can be so readily applied to the more advanced ages, that they need not here be further discussed. Exercise, however, demands some additional notice. Boys enjoy this freely, and of the best kind, in the unrestrained indulgence of their youthful sports. By means of these every muscle of the frame comes in for its share of active exercise, and free growth, vigour, and health are the result. It would be happy for girls if some portion of such latitude were allowed to them also. But it is far otherwise. Even under the more favourable circumstances of country life, they are too much restricted from the free exercise which health requires. Their very dress unfits them from taking it, and the alleged indecorum of those active movements to which youth and spirits instinctively incite, is a bar to even the attempt being made. At their age the measured, slow-paced, daily walk is quite insufficient even for the muscles specially engaged, while it leaves many others wholly unexercised. If this be true of the more hale and robust inhabitants of the country, how much more forcibly does it apply to the delicate and attenuated residents of towns, and especially to the inmates of female schools. Of these establishments the systems and habits require much revision, and until some effective reformation takes place, of which there is yet but little prospect, they will not fail to excite our sympathy and regret for the blanched aspects, shadowy forms, and sickly constitutions so continually presented, and which it is so painful to witness. Such beings are as little fitted for encountering the toils or fulfilling the duties of life, as are plants of a hothouse for being transferred to the open borders.\*

\* The amount of exercise, or rather the extent to which the *want of exercise* is carried, in many boarding-schools, will appear incredible to those who have not personally investigated the subject. The following is the *carte of a young ladies' boarding-school*, drawn upon the spot, a few years since, from the report of several of its inmates:—

- At 6 in the morning the girls are called, and rise.
- From 6 to 8, learning or saying lessons, *in school*.
- 8 to 8½, at breakfast.
- 8½ to 9, preparing lessons *out of school*, (some of the girls permitted to do so in the garden.)
- 9 to 1, at various tasks, *in school*.
- 1 to 1½, out of school, but must not go out of doors; reading or working, and preparing for dinner.
- 1½ to 2, at dinner.
- 2 to 5, in school, various tasks.
- 5 to 5½, tea.
- 5½ to 6, preparing to go out; dressing, or reading, or playing *in school*.
- 6 to 7, walking, generally arm-in-arm, on the high-road, many with their books in their hands, and reading.

By the foregoing statements we do not mean to cast the slightest reflection on those by whom these seminaries are superintended. We have ever found them most solicitous for the health of their pupils, sedulous to preserve it, and when disease arose, unremitting in devoted attentions. But the system is faulty, and for this they are not accountable. By the influences and prejudices which uphold that system, they, like others, are chained; and until the system itself yield to increasing knowledge, juster views of the animal economy, a more correct conception of mental energies and of the injuries which their over-citement occasions both to themselves and to the bodily frame, and a firm resolution not to barter health for vain accomplishments;—in other words, until both mental and physical education undergo

Two days in the week they do not walk in the evening at all, being kept in for *dancing*; but, by way of amends, they go out on two other days, from 12 to 1, and then they miss *writing*. It is to be remarked that they *never go out unless the weather is quite fine at the particular hours allotted for walking*. They go to church, all the year round, twice every Sunday, on which day no other exercise is taken.

From 7 to 8, for the older girls, reading or working in school, (this is optional,) and then prayers; for the younger, play in school, and prayers.

At 8, the younger go to bed.

From 8 to 9, the older, reading or working, as before. 9, to bed.

The twenty-four hours are, therefore, thus disposed of:—

	Hours
In bed, (the older 9, the younger 10,) .....	9
In school, at their studies and tasks .....	9
In school, or in the house, the older at optional studies or work, the younger at play .....	3½*
At meals .....	1½
Exercise in the open air .....	1
	<hr/> 24

The above account was taken from a second or third-rate school, and applies more particularly to the season most favourable for exercise,—*summer*. It is to be remarked that the confinement is generally greater in these than in schools of a higher order. That the practical results of such an astounding regimen are by no means overdrawn in the preceding pages is sufficiently evinced by the following fact, a fact which we will venture to say may be verified by inspection of thousands of boarding schools in this country. We lately visited, in a large town, a boarding-school containing forty girls; and we learnt, on close and accurate inquiry, that there was *not one* of the girls who had been at the school two years (and the majority had been as long) that was not more or less *crooked*! Our patient was in this predicament; and we could perceive (what all may perceive who meet that most melancholy of all processions—a boarding-school of young ladies in their walk) that *all* her companions were pallid, sallow, and listless. We can assert, on the same authority of personal observation, and on an extensive scale, that scarcely a single girl, (more especially of the middle classes,) that has been at a boarding-school for two or three years, returns home with unimpaired health; and, for the truth of the assertion, we may appeal to every candid *father* whose daughters have been placed in this situation. Happily, a portion of the ill health produced at school is in many cases only temporary, and vanishes after the return from it. In the schools in which the vacations are frequent or long, much mischief is often warded off by the periodical return to the ordinary habits of healthful life; and some happy constitutions, unquestionably, bid defiance to all the systematic efforts made to undermine them. No further proof is needed of the enormous evil produced by the present system of school discipline than the fact, well known to all medical men, that the greater proportion of women in the middle and upper ranks of life do not enjoy even a *moderate* share of health; and persons, not of the medical profession, may have sufficient evidence of the truth, by comparing the relative powers of the young men and young women of any family in taking bodily exercise, more particularly in *walking*. The difference is altogether inexplicable on the ground of sex only.—J. F. EDITOR.

\* Younger only two hours and a half.

considerable reformation and be founded on more rational principles, the evils must exist to an extent which no superintendent of a seminary can control. We are sorry to be compelled by truth to add that we have often found the same pernicious regimen carried to as great a height, although on a smaller scale, in private families, under the eye of a fashionable governess and a fond but injudicious mother.

Hurried breathing, short cough, palpitation, constitute a state of indisposition ere actual disease is considered to exist. Weak back, with incipient curvature of spine, in time aggravate these deviations from health. Irregular bowels attend, impairing still further the general health, and giving rise also to special ravages of the most formidable kind. A hard and tumid abdomen follows, the precursor and eventually the index of mesenteric derangement, which, next to phthisis, is perhaps the most intractable malady of youth with which the physician has to contend. Other evils, referable to the erroneous system and to the debility occasioned by it, may also be seen. Of these, chilblains are very common, and, when they occur, add greatly to suffering and to the further decline of health. They arise from failure of circulation, and, locally considered, are analogous to frost-bitten parts; being in fact so many partial mortifications resulting from loss of vitality in the capillary vessels. The surgical treatment which they receive is not always judicious. Regarded too much as local sores, and the irritability which they display being too much heeded, rest is enjoined, and thus even the insignificant exercise previously taken is suspended. Far better would it be, when this evidence of impaired vigour presents itself, to disregard the local ailment, and look solely to the constitutional state in which the local malady has its origin.

It is a prevalent opinion with teachers and parents that it is more conducive to the progress of education to keep a child at school when in infirm health, where the studies may still be continued, at least in some degree, than to interrupt them entirely by a removal to the parental roof. This is a great and often a fatal mistake. By such delay nothing is lost that can under such circumstances be accomplished: feebleness of body is little favourable to the full exercise of mental energies. Mental faculties depend for their manifestation and exercise on bodily organs, and in proportion as the organs are weakened, does the vigour of the faculties decline. By suffering both organs and faculties therefore to acquire renewed vigour, powers of effective exertion are recoverable to an extent fully capable of compensating for the temporary inactivity. It is a great mistake to conceive that education advances in proportion to the time devoted to it, or to the earnestness with which it is pursued. Mental powers are capable of a certain exertion only, and if they be overstrained, or too assiduously employed, they weary and decline, accomplishing much less than, with unimpaired vigour and more moderate exertion, they would be capable of doing in much less time. Every student is conscious of the inequality of his mental powers under different states of bodily health and different degrees of mental weariness, and fully sensible how little progress he makes when a

forced effort is required. The mind, too, requires variety of exercise in order to employ and gratify the various faculties of which it consists, and if it be chained down to a few objects, and especially if these be little congenial to its prevailing tastes and capabilities, the labour turns to little account. Under the systems of education which prevail, years are wasted in pursuits which ought not to occupy a tenth part of the time, if their value were rightly estimated, and the real powers of the mind properly directed. And this leads us to consider, what has hitherto been but too little influence in conducting education, the direct influence which the exercise of the mental powers has on the bodily health.

In the few following remarks on this subject we shall draw freely from an admirable paper published in the sixth volume of the *Phrenological Journal*, entitled "On Mental Exercise, as a Means of Health." The principles inculcated are of the highest importance, and though emanating in this instance from phrenological views, they have also so sure a basis in established physiology, that they may be beneficially applied even by those who still close their eyes to the truths of a science in which the writer of this article has no hesitation to avow his firm belief; and which, justly estimated, has more power of contributing to the welfare and happiness of mankind than any other with which we are acquainted.

The importance of muscular exercise as a means of preserving and improving health is generally admitted. It ministers to the health of the body, and, as the brain has its due share of this advantage, mental energies are also promoted by it. "But there is great reason to believe that exercise of mind, regular active employment both of intellect and of moral feeling, of which the various parts of the nervous system are the organic media, contributes so essentially to the well-being of the whole system, that it cannot be neglected without inflicting positive injury; and that, independently of its mental advantages, it is necessary to the enjoyment of full physical health." It is essential to health that the functions of the nervous system be well performed. But the intellectual powers, with the affective and moral feelings, form a part of these functions, and so intimately connected are the physical and mental energies that they mutually influence each other; so that, in proportion as nervous stimulus is unduly expended on the one, it becomes withdrawn from the other. Deficient or irregular exercise of nervous functions gives rise to much suffering, and in no class of beings more signally than in that to which so much of this essay has been devoted, namely, of young females of the upper and middle ranks, more especially those "of a delicate and nervous constitution, who, without any existing disease, without even having undergone any severe indisposition sufficient to debilitate the system, are nevertheless habitual invalids, and can scarcely venture beyond the limits of the drawing-room, or withdraw themselves from the rays of the sun, without some evil, real or imaginary, instantly overtaking them, and forcing them back to their retreat."

Some of the sources of this extreme delicacy, and the means of remedying it, it has been the

object of the foregoing pages to explain. "Young men of the same rank suffer infinitely less, because the constantly recurring calls of business and public life operate upon them as stimuli, and, in spite of themselves, exercise the feelings and employ the intellect on objects of some permanent value and importance, and thus keep up a stir of life and excitement of the system which is favourable to the health of all the functions, and to which unhappily many of the opposite sex remain, especially in their youthful years, altogether strangers."

"The three grand sources of vitality, failure or weakness of which may induce infirm health and delicacy of constitution, are the digestive, the sanguiferous, and the nervous apparatuses; and, accordingly, whenever great debility is observed to exist without any marked local disease, its true cause will almost to a certainty be found in weakness or deficiency affecting one or other of the three great systems of organs just named. If digestion, for instance, be radically feeble, then the chyle or nutritive material will fail, and weakness follow. If the lungs and circulating system be weak, the respiration will be imperfect, and the blood being inadequately acted on by air, its composition will be impaired, and, sent in this state through the blood-vessels, it will no longer afford the usual stimulus and support to any of the organs, and hence again constitutional delicacy. And, lastly, if the nervous functions be defective, not only will the mind suffer, but all the functions of the body will participate with it in languor, because all of them will receive a diminished and vitiated supply of nervous stimulus, a due share of which is essential to their healthy action."

The digestive, respiratory, and sanguiferous functions have been already noticed so far as the purposes of this essay require. It remains, then, only to pursue the consideration of nervous functions as involving and affected by the exercise of mind. So dependent is every part of the frame on the brain and nerves, that if the communication between them be cut off or obstructed by dividing or compressing the nerve which conveys nervous influence, the function of the part, however healthy it may be in every other respect, will cease, be diminished, or otherwise disturbed. When any organ, too, is stinted of its due share of nervous stimulus by the too great activity of some other part absorbing more than its own proportion, the function becomes weakened. Thus a diminution in the tone of all the other organs of the body will be experienced during an over-excitement of a few in writing or thinking intently, processes during which the vital actions and nervous energy are so much concentrated in the head, that from pure want of it the extremities become cold, and the action of the heart is lowered so as to weaken and retard the pulse, thus showing that a weak and inactive nervous system must exert an unfavourable influence on the general health.

For guidance in strengthening and developing the nervous system so as to render it fit for the adequate performance of all its functions, we must look to the general principles of physiology and the dictates of experience. "When any living part is called into frequent and regular exercise,

especially if the system is not yet arrived at full maturity, it is observed to become gradually more and more susceptible of action; to increase in size within certain limits determined by the constitution; and thereby to gain strength, as indicated by an increased power of enduring fatigue, and a greater capacity of withstanding the influences of the common causes of disease to which previously it would have yielded almost immediately. The physiological explanation of this, as proved by experiments, is, that exercise causes an increased action in the nerves and blood-vessels of the part, by which its vitality is augmented, and a greater supply of blood and nervous stimulus sent to it to sustain and repair the greater waste that is taking place, and also to supply additional substance to fit it for the unusual demands made on it. The results of this process are visibly exemplified in men whose habits or profession lead them to constant muscular exertion; in sportsmen, for instance, in blacksmiths, dancers, porters, &c.; and if it is less manifest in other parts of the body besides the muscles, it is only from other tissues admitting of less expansion, and showing their increased power in a different way. The improvement of the memory is a familiar instance of an increase of mental power produced by exercise; and the beating sense of fulness and quickened circulation in the head induced by intense study or thought, shows that an organic process goes on when the brain is in activity, similar to that which takes place in the muscular system under exercise." On the contrary, when the organ is little used, little expenditure of its power and substance takes place, little blood and little nervous energy are required for its support, and therefore little is sent; nutrition in consequence soon becomes languid, and strength impaired. To all these laws the brain is subject equally as the rest of the body. Frequent and regular exercise gives it susceptibility of action, with power to sustain it, the nervous energy acquiring strength as well as the vascular. Disuse of its functions, or, in other words, inactivity of intellect and of feeling, impairs its structure, and weakens the several powers which it serves to manifest. The brain, therefore, in order to maintain its healthy state, requires to be duly exercised; and as it consists of several parts, each performing its proper function, and as what holds good with respect to the whole collectively, is equally true of each part individually, it follows that for healthful and adequate exercise every function requires its due share of employment, else not only do the portions consigned to inactivity become impaired, but the general health becomes deranged by the irregular distribution of nervous stimulus thus occasioned. But such is the nature of the mental functions, that each must be excited by its proper stimulus, or both it and the portion of brain subservient to it are consigned to inactivity and consequent loss of power. No one would think of exercising the eye by sound, or the ear by colours. The effect of mere quiescence arising from the want of appropriate stimulus is signally manifested in the case of persons, and especially of the young, who in one situation manifest certain faculties very feebly, out who, when removed to another in which appropriate and adequate stimulus is supplied,

evince powers such as they were never previously supposed to possess. When we consider how few of all the faculties which the mind possesses are duly exercised in the courses of education, both for males and females, which prescription, prejudice, and fashion have ordained, we can have little difficulty in comprehending how nervous derangements of various kinds result from causes so efficient in producing them. "An appropriate example may be found in the case of a nervous young lady, whose education has communicated nothing but accomplishments, who has no materials of thought, and no regular and imperative occupations to interest her and demand attention; who takes no active part in promoting the welfare and comfort of those about her; who looks to others for support and sustenance; and whose brain is in fact half asleep. Such a person has literally nothing on which to expend half the nervous energy which nature has bestowed on her for better purposes. She has nothing to excite and exercise the brain, nothing to elicit activity; her own feelings and personal relations necessarily constitute the grand objects of her contemplations; these are brooded over until the mental energies become impaired; false ideas of existence and of providence spring up in the mind; the fancy is haunted by false impressions; and every trifle which relates to self is exaggerated into an object of immense importance. The brain, having literally nothing on which to exercise itself, becomes weak, and the mental manifestations are enfeebled in proportion; so that a person of good endowments, thus treated, will often exhibit something of the imbecility of a fool. But suddenly change the circumstances in which such a person is placed; suppose, for example, that her parents lose their health or fortune, and that she is called on to use her utmost energies in their and her own behalf; that in short her brain and mental faculties, her intellect and her moral and social feelings, are blessed with a stimulus to act; the weakness, the tremors, the apprehensions which formerly seemed an inborn part of herself, disappear as if by enchantment; and health, vigour, and happiness take place, solely because now God's law is fulfilled, and the brain with which he has connected the mind is supplied with that healthful stimulus and exercise which he ordained to be indispensable to our comfort and welfare."

We once attended a young lady for various nervous complaints, who possessed the most exquisite sensibility of frame we ever witnessed. For years she had endured almost every form of the most aggravated hysteria. She was brought up with every refinement of education, and the habitual indulgence of every luxury, her parents appearing to live only for the purpose of ministering to her gratifications. Such was her acuteness of sensibility that at certain times the mere opening or closing of a door was agony; such her helplessness, that oftentimes she could scarcely muster energy enough to raise her hand to her head. In the midst of this her father became bankrupt, and soon after died. His family were now obliged to labour for their support, and on this feeble creature devolved much of the care of providing them subsistence. She had talents, and she exerted them. With the assistance of friends

she opened a school, which she superintended with unremitting assiduity. Her nervous maladies vanished, and for years she persevered steadily in her altered but more happy course of life. It would have been fortunate if she had commenced this earlier; for the delicacy of constitution created by early mismanagement laid the foundation of phthisis, of which she eventually became a victim.

While inactivity of brain leads to evil, over-excitement is no less injurious; and if persisted in without suitable relaxation, exhaustion and permanent weakness are the results. In ordinary education both errors are committed. The mental powers exercised are too few, and these are continually overworked, while the larger portion is left to chance for obtaining any exercise at all. In education, too, attention is too exclusively directed to the intellectual powers, while the effective and moral faculties are unheeded, or only acted on through the intellect. And yet they admit of rational culture equally as the intellectual powers, while on them and on their government do the virtue and happiness of mankind far more depend. Intellect is no doubt capable of assisting in this government, but never can the moral feelings be disciplined through intellect alone. Ethical discourses, the most eloquent and conclusive, may be pronounced, but alone they reach not the heart. The moral sentiments, to be truly cultivated, must be felt; objects must be presented capable of exciting emotions; and then intellect may interpose to assign the just limits of their indulgence. No discourse on charity can have the effect of a real opportunity for doing a benevolent action. No lecture on justice can make impression equally as an occasion of exercising this quality, especially where other incitements opposed to it require to be overcome. A conquest thus gained does more to confirm the principles, from the deeper impression made by a practical example beyond that of a speculative rule, and from conscious satisfaction and heartfelt pleasure derived from every victory over self, when once the victory is completed, than all that the most profound moralists ever wrote. The minds of the young should be exercised in all the faculties by which their social condition in after-life is to be maintained, and in this some attention should be given to the natural order of their development; for some precede others in activity, and also become more quickly matured. Most of the affections and moral sentiments may be observed in their manifestations even in the cradle. Of the intellectual powers, those which are employed in acquiring a knowledge of the external world are earliest developed. The reflective faculties advance more slowly, and hardly attain full power until the body reaches its full growth. Much of our ordinary courses of education is in opposition to these facts. Many of our classical books which mere boys are condemned to read, require not only mature intellect, but considerable knowledge of the world for their comprehension.

The object of education is to fit human beings for maintaining their social relations, and performing all their several duties in life. For this end they should learn the properties of bodies, and also the qualities by which men act on these and

on each other. Minute and intimate knowledge of all these it would be impracticable for any individual to attain, nor is it necessary; but an outline of them is within the reach of all, and this, which to any ordinary capacity would be only pleasurable acquirement, may prove of much practical utility, while by exercising the cerebral organs it will invigorate both these and their functions, be a source of much pure gratification, withdrawing the mind from selfish and sensual pursuits, and through its manifold influences have a beneficial effect on the general health. The various branches of natural science are among the best exercises on which the young mind can be employed; for while they engage a large number both of the knowing and reflecting faculties, they incite also several of the higher sentiments by presenting to the mind the wisdom and goodness of the great Creator, so abundantly displayed in all his works; the benevolent purposes for which all these are designed, the good which they impart, and the happiness which they diffuse. Such contemplations withdraw the mind from selfish passions, consigning them to that quiescence which lightens the task of keeping them under due control.

Above all other studies, however, that of the mind itself is the most interesting and the most important. By it alone can we form a just estimate either of ourselves or others, or have any clear conception of the powers with which nature has endowed us. Some knowledge of these powers must be of material assistance to us in regulating their exercise, ascertaining their objects, and restraining their excesses. The subject, however, is far too copious for this place, and unsuited for the present occasion. What has been adduced was necessary in order to convey any conception of the influence of mental actions on the bodily frame, and to show the intimate connection that subsists between mental and physical education. That the foregoing sketch of the latter is far from complete we are well aware. Many points of detail have been passed over or slightly noticed, which would admit of more copious illustration and more explicit instruction. If we mistake not, however, enough has been advanced to display the principles on which physical education should be conducted; and an outline at least has been furnished which each reader may readily fill up according to his intelligence, and to the condition of life to which it is to be applied.

E. BARLOW.

**ELECTRICITY.**—When a substance has acquired the power of first attracting and then repelling light bodies placed in its vicinity, and of emitting sparks, it is, in the language of electricians, said to be *excited*. These phenomena, we are told, were first observed by Thales of Miletus in a piece of amber, which by the Greeks was called *ήλεκτρον*, and hence the origin of the term electricity.

Electricity may be developed by several means, the chief of which are friction, the contact of dissimilar substances, pressure, variations of temperature, and chemical action. In the present article we shall confine ourselves to the first-mentioned source, and shall dwell even upon it no further than may be necessary for rendering intelligible

what we shall have to say respecting the therapeutic applications of the electric fluid.

When a glass rod is rubbed with silk, and then brought close to a little sphere of elder pith suspended by a silk thread, a combination commonly called an electric pendulum, the sphere is first attracted by the glass, and, upon contact, immediately repelled. But upon substituting for the glass rod one of metal, no such phenomena will be observed. Such experiments have suggested a division of bodies into two classes, the electrics and the non-electrics, or those which admit and those which do not admit of being rendered electric by friction. Glass, sulphur, wool, silk, and all resinous substances are electrics. Carbon, the several metals, water, and every variety of organized substance, in consequence of the water which all such include, acid and saline solutions, &c. are non-electrics. This division, however, we shall presently find to be based upon an erroneous supposition. All bodies, in fact, are electrics; and if there are some which, under ordinary circumstances, do not appear to become excited by friction, it is because the electricity is permitted to flow from them into the earth as fast as it is generated.

This brings us to another division of bodies, having reference to their electrical relations, founded on a different principle, namely, that which resolves them into conductors and non-conductors, or rather into those which are with facility and those which are with difficulty traversed by the electric fluid; for, strictly speaking, there is no absolute non-conductor. If a glass rod be applied to an excited body, it will become electrified merely at the point of contact. But if a metallic rod, suspended upon silk, be applied in a similar manner, it will at the same instant exhibit symptoms of excitement at every point. This simple experiment illustrates sufficiently the difference of the conducting powers of the two rods.

When a body is surrounded on every side by non-conductors, it is said to be insulated. Thus a ball of metal resting upon a cake of resin, or a stool with glass legs, or suspended by a silk thread, is insulated, for it is in connection with the earth only through the medium of non-conductors. If the insulation were perfect, the ball once electrified should continue so for an indefinite time. In practice, however, this never occurs, for the reason already assigned, namely, that there are no absolute non-conductors. Dry air is probably the best insulator with which we are acquainted; but, by impregnation with aqueous vapours, it acquires conducting powers.

The two divisions just noticed admit of being reduced into one, the electrics being non-conductors, and the non-electrics conductors. It is, in fact, owing to this latter coincidence that some bodies appear incapable of being excited. Thus, if a disc of copper, held in the hand, be rubbed with a silk handkerchief, it does not become excited; but if, before the application of the friction, it be insulated, the usual phenomena manifested by electrics will present themselves.

In every case of electrical excitement two distinct powers are contemporaneously developed. Thus, when glass is rubbed by silk, both become electrified, as may be proven by approaching them

in succession to an electric pendulum. The electricity of the glass, however, is different from that of the silk, for when either is communicated to two contiguous pendulums, these repel each other. But when the electricity of the glass is communicated to one pendulum, and that of the silk to the other, attraction ensues. These different powers require to be designated by different names, and hence the terms *vitreous* and *resinous*, which, whatever be the substances rubbed, are applied to the distinct energies developed by the process of friction. Such was the language of Dufay. But, in more modern times, these designations have been by some replaced, particularly in Great Britain, by the terms *positive* and *negative*, introduced by Franklin, the former corresponding to the vitreous, the latter to the resinous electricity of Dufay. This difference of nomenclature depends upon the different opinions entertained by these philosophers respecting the nature of the electric influence. Dufay viewed it as a compound, Franklin as a simple fluid. The former referred all electrical phenomena to the resolution of the compound into its vitreous and resinous elements. The latter explained them by supposing that all bodies, in their natural or neutral state, contain a certain quantity of the electric fluid, and that the processes, which produce electrical excitement, operate merely by disturbing this proportion, and thus causing an accumulation in some and a deficiency in others. We shall not enter here into any criticism upon the respective merits of these rival hypotheses. Suffice it to say, that the theory of Dufay is that adopted by the highest authorities in science, principally, as it would seem, because of its analogy to that which is alone applicable to the kindred subject of magnetism.

In order to a consistent explanation of all known electrical facts, it is only necessary to suppose, with Dufay, that electricities of the same name repel, and of contrary names attract each other, and with a force varying in the inverse ratio of the square of the distance. This principle of the action of the elementary fluids at a distance is applicable to a multitude of phenomena, amongst others, for example, to the charging of the Leyden phial. By electricians it is known under the name of *induction* or *influence*. It may be illustrated by the attraction already noticed as occurring when we approach an excited glass tube to an electric pendulum. The vitreous electricity of the tube decomposes the natural fluid of the ball of the pendulum, attracting its resinous and repelling its vitreous element; the attraction, however, being more energetic than the repulsion, inasmuch as it is exerted at a shorter distance. But, as the ball is insulated, its constituent electricities are merely separated from each other, but cannot leave it; hence it will itself be carried towards the tube, and with a momentum corresponding to the difference of the opposed forces.

There is but one point more connected with the theory of electricity to which it is necessary to advert here. When a body is electrically charged, the free electric fluid is confined solely to its surface, and does not, as experiment proves, dip to any appreciable depth into its substance. Its distribution, however, on the surface is never equable,

except in one case, namely, when the body is a sphere. In all other solids it accumulates in greatest quantity upon the most prominent or projecting points. But the tendency of the electric coating of an excited body to escape, is, as Laplace has shown, proportional to the square of its thickness. Hence we deduce the practical inference that a body studded with points cannot be strongly charged, for before much free fluid has been communicated to it, such a quantity will have accumulated at the points as to flow out in a continued stream, by forcing a passage through the atmosphere.

Having disposed, in this short summary, of the principles of electricity, we shall now briefly describe such articles of electrical apparatus as are indispensable with a view to its application as a medicinal agent. These are the machine, the insulating stool, the director, the Leyden jar, and the discharging electrometer.

The electrical machine is the piece of apparatus employed for the purpose of obtaining electricity in considerable quantity. It consists essentially of three parts; the rubber, the substance rubbed, and the conductor or conductors, for there are sometimes two of them. The substance rubbed is invariably of glass, and is sometimes a flat disc, but more usually a cylinder. By a winch handle, attached to one extremity of its axis, a motion of rotation is given it, and it is thus made to slide upon the rubber, which is nothing but a leathern cushion, to which a small quantity of an amalgam (composed of one part of tin, two parts of zinc, and six parts of mercury) is usually applied, and to which is appended a flap of silk, which embraces the semi-circumference of the cylinder, or, in the case of the *plate*, in which there are two cushions, extends from an extremity of the vertical to one of the ends of the horizontal diameter. The friction exerted between the glass and the rubber effects a continued decomposition of the electric fluid residing on their common surface, the vitreous or positive element being determined to the glass, and the resinous or negative element to the cushion. The latter passes at once to the negative conductor which is in contact with the rubber,\* and from it, if uninsulated, into the earth. The former develops, by the process of induction, electricity of the same name in the positive conductor, which is an insulated metallic cylinder, or system of cylinders, straight or curved, presenting to the glass a number of points, which are placed at a distance from it not exceeding a quarter of an inch. When positive electricity is required, the negative conductor must be uninsulated, by hanging upon it a metallic chain so that it may reach the ground. On the other hand, when negative electricity is required, the negative conductor is insulated, and the positive one put in connection with the earth. In order that the machine may work well, it is necessary that it be rendered perfectly clean and dry, by placing it before the fire, and rubbing it carefully with silk or flannel. Especial care must be taken that the conductor of which the electricity is wanted be well insulated, and this is best ensured by gently

heating its glass leg; for the deposition of hygro-metric moisture upon it is thus rendered impossible.

The nature of the insulating stool is announced by its name. The back may be of any material, but the legs are invariably of glass, this being the strongest of all non-conducting substances.

The director is a brass rod of about a foot in length, terminating at one end in a ball of the same metal, and at the other in a glass handle. The ball admits of being screwed off, and, when removed, exposes to view the extremity of the director ending in a fine needle-point. This point should also screw off, for the purpose of being occasionally replaced by one composed of baked wood, or of brass covered with lac varnish.

The Leyden jar is a cylindric glass vessel, coated within and without to about two-thirds of its height with tin-foil, and closed above by a wooden plug perforated by a brass wire, which terminates outside in a ball or knob, and inside in a chain prolonged so as to reach the inner coating. To charge the jar, its knob is made to touch one of the conductors of the machine while in action, its outer coating being, at the same time, uninsulated by being held in the hand, or in any other way put in connection with the earth through conducting substances. The inner coating obviously acquires the electricity of the conductor which it touches, while the outer surface becomes, at the same time, charged with the opposite fluid in virtue of the principle of *influence*. To *discharge* the jar, the two surfaces are to be connected by some good conductor. Thus, upon applying one end of a metallic wire to the outer coating, and approaching the other to the ball or knob, the opposite electricities rush together, presenting the phenomena of the spark,—that is, a flash of light accompanied by a sharp snapping sound, and both surfaces return to the natural state.

Of the discharging electrometer there are many modifications. It is, however, essentially nothing but a brass rod terminated by balls, and supported in the horizontal position by a glass leg. If, while a jar is charging, one end of the rod is placed within one-eighth of an inch of its knob, the other extremity being connected, through some conductor, with the outer coating, a very slight charge will cause the spark to pass between them. If the distance be now increased to a quarter of an inch, a stronger charge must be communicated to the phial before its spontaneous discharge will take place, and so on, so that, by properly adjusting the distance, we can regulate the maximum charge at pleasure.

When a spark is taken by approaching the knuckle to a machine in action, it causes a peculiar pungent sensation, the nature of which it is not easy to convey by description. Generally speaking, however, when thus produced, it is not, unless the machine be very powerful, accompanied by much pain. But if a loaded jar be discharged through the body, which may be readily done by applying one hand to the external coating and the other to the knob, a sensation of an exceedingly distressing kind will be experienced, which is usually and very appropriately denominated the *shock*. The distance to which the shock extends

\* In the plate-machine there is no negative conductor, the cushions being, through the wooden frame, in connection with the earth.

depends upon the magnitude of the coated surface and upon the intensity of its electricity. Thus, with a certain charge, it is felt at the wrists, with a stronger at the elbows, and with a still stronger, even at the chest. A surface of thirty square inches, when loaded by a common machine, is capable of destroying mice and small birds, and there are few individuals of the human species who can receive with impunity the maximum charge of a square foot, or one hundred and forty-four square inches. It is worthy of remark that the bodies of animals destroyed by the electric shock are very prone to putrefaction, that the irritability of the muscular system seems almost entirely destroyed, and that their blood does not coagulate. Similar observations have been made upon animals struck by lightning.

The influence of the shock seems particularly directed to the nervous system. A small charge passed through the head of a bird deprives it of sight, and a considerable one received in the head by Mr. Singer had the effect of a violent blow, and was followed by a temporary loss of memory. When a jar is discharged along the spine of a person in the erect position, the action of the muscles is for a moment suspended, and he falls to the ground. Electricity, therefore, produces a paralyzing effect when brought to bear upon the centre of the nervous system. But when transmitted to the muscles of a limb, the invariable consequence is their spasmodic contraction, and this is true even though the member be in a paralytic state. Some recent researches, which will be noticed under the head of GALVANISM, render it highly probable that the muscles are not directly sensible to the stimulus of electricity, but that they are thrown into convulsive action by the electric fluid, merely because of its traversing the nerves by which they are supplied.

Electricity was very early employed as a therapeutic agent, and is even still resorted to by physicians, though it has lost much of the celebrity which it once enjoyed. The diseases in which it is applied are the different forms of paralysis, including amaurosis and deafness when functional affections, epilepsy, hysteria, chorea, chronic rheumatism, particularly those forms of it which produce stiffness of the joints, cases of retention or suppression of the menstrual flux, nervous headaches, and local pains unconnected with inflammation, asphyxia produced by drowning or the irrespirable gases, enlargements and obstructions of the glandular system. These are the affections for which it is still prescribed, and occasionally with success. But there is scarcely a disease in nosology for which it has not at one time or another been recommended.

As a remedial agent, electricity may be applied in five different ways. The first method, which is, we believe, at present employed, is to *excite* the patient by placing him upon an insulating stool, and putting him in connection with the prime conductor of a machine in action. This is what is called the electric *bath*. It was strongly recommended by Priestley, apparently under the impression adopted from the Abbé Nollet, that the animal functions are, under such circumstances, discharged with increased vigour, particularly the circulation of the blood and the cutaneous

secretion. Such effects are sometimes observed, but by no means invariably. The bath was employed by Lit and De Haen, two early writers upon medical electricity, for the treatment of hysteria.

The next and simplest method of applying electricity to the cure of disease is to present the member, or part affected, to the prime conductor of the machine, and thus cause it to receive a succession of sparks; or, what is more convenient, to place the patient on a chair, and convey to him the sparks by means of a director connected with the conductor by a chain. The patient may manage the director while the operator works the machine.

The third mode consists in placing the patient upon an insulating stool, putting him in connexion, through means of a chain or metallic rod, with the prime conductor, and drawing sparks from the seat of disease or pain by simply presenting to such part the knuckle, or, should the operator dislike receiving the spark himself, an uninsulated director. This method of operating has the advantage over the preceding that it conjoins the electrical bath with the influence of the spark. It is, therefore, that usually adopted by those experienced in the medicinal administration of electricity. The force of the spark is proportionate to its length, so that, by properly diminishing this, its strength may be reduced to any required standard.

A favourite mode with some practitioners of applying sparks is to *give* or *draw* them across flannel. For this purpose, a director, terminated by a large ball, which is to be covered with a fold of flannel, is approached in the usual way to the organ to be electrified. Instead of a single strong spark, a series of weak ones will thus be produced, which, emanating at the same instant from several of the woollen fibres, extend over a considerable surface and produce in it a peculiar pricking sensation. The ball of the director may be naked, the flannel being laid on the part of the body which is to be submitted to the influence of the sparks. This method is supposed to be particularly suited to the treatment of rheumatism and paralysis, especially in patients who cannot endure the stronger forms of electricity.

The next form of medical electricity to be noticed is the *aura*, or jet of air, which proceeds from an electrified point. This is the modification of the electric influence to which ulcers, excoriated surfaces, and delicate organs, such as the eye and testicle, are usually subjected. The common method of employing the aura is to present a pointed director, connected by a chain with the conductor of the machine, and held by a glass handle, to the part affected. The particles of air in contact with the point are highly electrified, and, of course, immediately repelled. The same occurs to those which take their place, and so on in succession, producing a current of highly excited air, which, as has been just described, is directed upon the organ which is the subject of electrical treatment. The aura may also be applied by placing the patient upon an insulating stool, and directing an uninsulated pointed director to the seat of disease. It is, however, seldom resorted to, as its efficacy is more than questionable.

When the point which terminates the director is of baked wood, this being a bad conductor, the electricity does not issue in a continuous stream, but as a succession of minute sparks, which produce in the part of the body upon which they are directed a sensation perfectly similar to that which attends electrization across flannel. This kind of electricity is applicable to cases where the aura is not sufficiently energetic, and where the sparks proceeding from a ball are found too pungent.

For the application of electricity to deep-seated parts, such as the exterior of the mouth or the bottom of the external meatus of the ear, a particular form of director has been devised, the description of which may with propriety be given here. A glass tube of about one-tenth of an inch internal diameter is left open at one end, and is closed at the other by a cork, through which there slides a brass wire, terminated within by a ball, which, as in the common director, screws over a point. To apply this instrument, the open end of the tube is introduced, we shall suppose, into the ear, and the external extremity of the wire being brought as close to it as may be deemed advisable, sparks, or the aura, are communicated or drawn in the usual way. The glass tube, being a non-conductor, prevents any lateral divergence of the electric fluid, and directs it upon the point placed immediately beneath its orifice.

When *shocks* are deemed necessary, we must have recourse to the Leyden jar, and this constitutes the fifth form under which electricity may be exhibited medicinally. The method, of course, consists in discharging a loaded jar through the affected part or member as often as may be considered advisable. The readiest method of accomplishing this is to place the free extremity of a copper wire, wound about the outer coating of a charged phial, in contact with one end of the course which it is intended to make the electricity traverse, and then bring the knob of the jar to the other end. When the knob comes within the striking distance of the body, the discharge takes place, and the shock is felt in the interval which separates the knob and wire. Against this method, however, the objection lies that we are not enabled to measure the amount of the charge, and that the shock, therefore, does not admit of being graduated according to the feelings of the patient, or the nature of the disease. To attain this object, it is necessary to interpose the discharging electrometer, already described, in the arc which connects the outer and the inner coatings of the phial. The knob of the jar being now placed in contact with the conductor of a machine in rotation, and at the selected distance from one of the balls of the electrometer, the discharge takes place as soon as the free electricities have acquired sufficient tension to force their passage through this interval, and a shock is felt in the part of the body which completes the circuit. If this be too strong, the ball of the electrometer must be placed at a less distance from the knob; if too weak, the distance between them must be augmented. The two parts of the body between which it is intended that the electricity shall pass are to be touched by the balls of two separate directors, held by an assistant, and connected, by means of

chains, the one with the electrometer and the other with the outer surface of the jar. Thus, if one of the directors be in contact with the hip, and the other with the knee, when the discharge takes place, the shock will be felt along the entire thigh.

This method of regulating the shock should be familiar to such as employ electricity in the practice of medicine. The discharge of a small jar proves fatal, as we have seen, to the smaller animals; and there can be no doubt but that by means of a battery of no very great surface human life might be destroyed. The power, too, of sustaining the shock is very different in different individuals, and even varies in the same person so as to differ at different times, and in different states of the system. These circumstances enjoin caution in the administration of electricity, particularly by means of the jar; and it may be added that, in point of fact, its injudicious and indiscriminate use has proved extremely injurious. To this effect may be quoted the case of a young girl labouring under paralysis of the right arm, related by Dr. Harte, (Phil. Trans. vol. iii.) who, after two shocks, became universally paralytic. From this state she was with difficulty recovered by judicious medical treatment, but relapsed upon being again subjected to three discharges of the Leyden jar. After the lapse of four months she was again relieved of the maladies inflicted upon her by electricity, and, nothing discouraged by his first failures, the doctor, it is said, would have resorted to the shock a third time, but Priestly quaintly observes, "the girl being more nearly concerned in the experiment than her physician, thought proper to decline it." The medical reader who resides in the vicinity of an electrizing quack will, no doubt, be able to call to mind similar cases.

In the employment of electricity as a curative agent, there are certain precepts to be borne in mind, without an attention to which disappointment will be often experienced, and unmerited discredit thrown upon a really efficacious means of subjugating morbid action. These may be reduced to the following heads.

1. Electricity should be only considered as auxiliary to other modes of medical treatment which experience has shown to be advantageous. Thus, in rheumatism, it may be combined with diaphoretics; in chorea, with tonics; and in paralysis, with medicines which, like strychnia, stimulate the nervous system, a practice recently adopted for the cure of palsy arising from the absorption of lead.

2. We should always commence with its weaker forms, such as the bath of aura, next proceed to sparks, and finally, should these prove insufficient, to shocks, taking care to regulate their strength by the means already described, and avoiding their exhibition, when of such degrees of energy as to prove distressing to the feelings of the patient. The sparks applied in amaurosis, or for the discussion of glandular tumours, must be feeble, and in such cases shocks are quite inadmissible. To communicate the latter, a jar, four inches in diameter and six in height, will be found amply sufficient, and its knob need never be placed at a greater distance from the ball of the electro-

meter than one-fourth of an inch. An interval of from one to two-tenths of an inch will, generally speaking, be sufficient.

3. The electrization should be performed daily, and be persevered in for at least a month, if necessary, and a cure must not be despaired of because there is no immediate relief experienced; for the good effects of electricity generally require a long time for being developed.

4. The *aura* may be applied for from five to ten minutes. The number of shocks passed in one direction should not exceed twelve, nor the number of sparks applied to the same part twenty-four.

5. In local affections, the electric fluid should be confined to the diseased part or organ. But in diseases, such as chorea and epilepsy, in which the entire system seems to be engaged, it must be applied generally over the body. Such parts, however, as are affected with pain, or any unusual sensation, should be particularly dwelt upon.

The *modus operandi* of electricity, in the cure of disease, is considered obscure. It would appear, however, in its ordinary forms to act as a simple stimulant. Upon the nervous system, indeed, it is by many supposed to exercise a particular influence, of the nature of which we shall be enabled to form some idea, should the hypothesis broached in modern times, and which refers the functions of the nerves to currents of electricity transmitted through them from the brain and spinal chord, turn out to be correct. We shall revert to this subject in the article *GALVANISM*, and shall here merely remark that, assuming the theory alluded to to be sound, it will be proper, in the medicinal administration of electricity, to cause the positive fluid to pass through the body always in the direction of the ramification of the nerves. This precept is particularly insisted upon by some foreign electricians.

The spark received from substances resinously electrified differs, in some respects, from that which issues from surfaces vitreously charged. It is more pungent, and has a different shape, being shorter, and not so regular in form. As medicinal agents, however, they appear both to produce similar effects. A contrary opinion has indeed been maintained by some, who have represented resinous electricity as a sedative, and vitreous as a stimulant. This theory, which is quite unsupported by facts, is not a modern invention. It originated in 1779, with Bertholon of Montpellier, who resolved diseases into two classes, those which depended on an excess, and those which were the consequence of a deficiency of the electric fluid, and treated the former with resinous, the latter with vitreous electricity. It is not necessary to enter upon any formal refutation of such an absurd hypothesis. In it, however, may be recognised the germ of the more celebrated but equally unfounded nosological notions put forward two years after by Dr. John Brown, in his "*Elementa Medicinæ*."

It has been long suspected, and indeed rendered almost certain by a variety of facts, that the electrical state of the atmosphere has an appreciable influence upon the animal economy. The lower animals seem aware of an approaching thunder-storm, as would appear from the uneasiness which

they manifest, the cries which they utter, and their running about in a state of alarm in search of shelter. Many individuals also of the human species, particularly those labouring under certain chronic complaints, or who possess what may be called a great degree of mobility of the nervous system, experience at such times very peculiar sensations. Observations such as these, and many others of a similar description which might be quoted, demonstrate very completely that the animal machine is frequently sensibly affected by the electricity of the atmosphere; and there is even nothing improbable in the conjecture which has been often hazarded, that the salubrity or insalubrity of particular districts and seasons, the existence and the character of epidemic diseases, are in some way connected with, if not immediately dependent upon, the same influence. Upon none of the many branches, however, of this interesting subject can we be said to possess positive knowledge. Experiments must be multiplied before we can acquire data to reason with any precision upon it. Indeed it is only within a few years that these could have been instituted with any prospect of success. Our means of research are at present sufficiently delicate to enable us to commence such an inquiry with advantage; and it is much to be wished that meteorologists may henceforward register the variations in the electrical state of the atmosphere with as much diligence as those which occur to its temperature and pressure.

JAMES APJOHN.

[ELECTRO-PUNCTURE.—See *GALVANISM*.]

**ELEPHANTIASIS.** There are two different diseases which possess this common name; they are usually distinguished by the epithets *Arabian*, or of the Arabians, and *Grecian*, or of the Greeks. We shall treat of them under these terms.

**ELEPHANTIASIS ARABUM, (*Elephant Leg*.)** The earliest account we have of this disease is by Rhazes, an Arabian physician, who lived in 850. In the Arabian language this affection is denominated *dal fil*, which imports literally *morbus elephas*, elephant disease. The Arabians sometimes contract *dal fil* into *fil*\* alone, literally, *elephas*, elephant affection. This appellation was applied to the disease by the Arabians, in consequence of the huge misshapen appearance of the affected limb being supposed to bear some resemblance to the form of the leg of an elephant.

Elephant leg is known in the West Indies by the name of *Barbadoes leg*; sometimes it is there denominated *yam* leg, from the supposed resemblance the affected extremity has to the fantastic forms which this root occasionally assumes. In Ceylon it is called *Galle* leg, and on the peninsula of India it is denominated *Cochin* leg, from its being indigenous to these places. In the Malabar language it is called *anay kaal*, a term which, like *dal fil*, imports elephant leg.

**Geographical Distribution.**—This disease is in a remarkable degree endemic in the island of Barbadoes, on the south-west coast of Ceylon, in the neighbourhood of Cochin, on the Malabar

\* *Fil* alfili, *Arabic*; ulfeel, *Sanscrit*; fil, ulfwall, elephant, *Greek*; elephas, *Latin*. (*Thomson*.)

coast, in some parts of Japan, in Egypt, and in Abyssinia. It occurs not unfrequently in almost all of the West India islands and British settlements of South America; in the Polynesian isles; and in the provinces of Castile and the Asturias in Spain. Sporadic cases occur over Europe generally, and perhaps in all parts of the world.

**Persons liable to this Disease.**—In Barbadoes elephant leg was, until about the year 1704, confined to the black population. A white inhabitant was attacked in that year; and before the year 1760, when he died, the disease was common among the white population. In general, it would appear that imported Europeans are not liable to the disease unless they reside for a considerable time in the island. It is perhaps owing to this circumstance that soldiers are very rarely affected with it.\*

In Ceylon the disease is confined to the indigenous inhabitants, including the half-caste and Creoles. Imported inhabitants, comprehending Europeans, Africans, Malays, or natives of the peninsula of India, may be said to be exempted from its influence. There is only one instance known of a native of Europe having become affected; and in his case the disease did not appear before he had been a resident at Point de Galle between thirty and forty years.

Soldiers and other imported Europeans are not liable to it at Cochin.

The disease affects all ages, although in general it appears in the early period of life; and, in some rare cases, in the first year. Both sexes seem to be equally liable to it, and no condition of life confers an immunity from its influence. Individuals who enjoy every comfort, and who are not exposed to great vicissitudes of temperature or changes of weather, are as liable to elephant leg as those who endure the hardships and privations of life.

**Symptoms.**—The constitutional excitement, or primary stage of this disease, generally comes on suddenly, with rigors, headach, nausea, pain in the back and loins; to these follow great heat of skin, alternating with profuse perspiration, and ardent thirst. Some particular part of the body (for, notwithstanding the name, the disease is not exclusively confined to the leg,) becomes red, hot, swelled, and painful, especially along the tract of the lymphatic vessels, so as to resemble, in some measure, an erysipelatous affection. The febrile excitement becomes lessened in two or three days, and soon entirely disappears. This circumstance is followed by a cessation of the local inflammatory symptoms, the heat, redness, and pain; and the swelling becomes also greatly reduced, although the part affected rarely returns to its natural size. Paroxysms of this kind succeed each other at intervals of various length, and frequently with some degree of regularity; sometimes they occur as often as once a month, and at other times not oftener than once in six months. Every successive attack adds to the effusion and consequent morbid enlargement of the part affected.

Every part of the body seems to be liable to

this affection. It has been observed in the head, the tongue, the neck, the breasts, the abdomen, the thigh, and the skin in general. The condensation of the cellular tissue of new-born or very young children is a form of elephantiasis. The parts most frequently affected are the superior and inferior extremities, the vulva, and the scrotum.

The internal organs are also liable to become affected. Is it not probable that some varieties of enlargement of the liver, and the sarcomatous morbid structure of the ovary and uterus, are kindred affections, if not the same?

Dr. Musgrave thinks this disease should be termed the *migratory inflammation of the lymphatic system*. He says, "whatever may be its original seat, the patient is never secure, while the constitutional disturbance subsists, from a sudden retrocession to some vital organ. I have seen it in the same case translated from the scrotum to the head, from thence, after some hours, descend with the rapidity of lightning to the abdomen; again migrate to the chest, to return perhaps to the encephalon and prove fatal there; or, under more favourable circumstances, resume its comparatively harmless situation, and run its subsequent course, as if nothing untoward had occurred; and, while occupying the different cavities, giving rise to the ordinary symptoms of acute inflammation of that particular viscus which it had selected for its temporary abode." (Edinburgh Med. and Surg. Journal, No. 92.)

It is not common for more than one part of the body to become morbidly enlarged in the same individual, although this circumstance sometimes occurs. A schoolmaster at Point de Galle had both arms and both legs affected. The scrotum is sometimes greatly increased in size: there was a mendicant at Galle, in whom it descended to the ankle, and who, when he sat to solicit alms, used to sit upon this part of the body, as he would have done upon the trunk of a tree! The leg is, we believe, the part of the body which is most frequently affected, and sometimes it becomes enormously enlarged. Occasionally the swelling is uniform; but commonly the skin is rough, rugged, and scaly, and the enlargement divided into unequal protuberances, which are intersected with deep fissures. The writer of this article was requested to visit a woman at Galle, who, although only about twenty-five years of age, had both of her inferior extremities so much enlarged and deformed, that the back part of the legs rested upon the ground and projected behind the heel, about nine or ten inches. The fissures and interspaces between the projecting and pendulous protuberances had ulcerated, and were discharging a most offensive sanies. Life could not be long preserved under such extensive disease.

**Organic Changes.**—This disease is evidently, in the first instance, constitutional; and the local affection seems to be a result of some form of the process of inflammation, which recurs at intervals. A quantity of sero-albuminous fluid is effused from the exhalents into the cellular tissue of the affected part, which is not removed by adequate absorption; and the part of the body that may be affected becomes tumid, hard, and misshapen.

Upon examination after death, the subcutaneous tissue of an affected limb is found hard, dense,

\* Dr. Hendy states that horses are liable to the disease in Barbadoes, and that it had been reported to him that dogs, horned cattle, and poultry, were sometimes affected with it.

and interspersed with small cells filled with serous fluid: the aponeurosis which covers the muscles is thickened, as also the cellular and intermuscular tissue. The muscles are less red than natural. The arteries and veins are commonly not materially altered.

It deserves to be remarked, that the effused fluid in this disease is always coagulated; it consequently differs much from the serous effusions found in anasarca or ascites. It is still unascertained why it is so seldom absorbed, and so rarely excites inflammation and consequent ulceration. This effusion appears to be extra-vascular, although the fluid does not seem to have the effect of an extraneous body.

**Remote Causes.**—We know nothing satisfactory respecting the remote causes of elephant leg. It is admitted to be comparatively a new disease in Barbadoes, in as far as imported, if not Creole whites are concerned; and no very important change has been observed in the climate of the island.

The aboriginal inhabitants of Demarara are not liable to this affection, although it is not rare among imported and Creole Africans and the half-caste. It occurs occasionally among the Creole whites; and perhaps there are about two cases of elephant leg in the colony among the imported Europeans. The progeny of Dutch families are more liable to morbid enlargements of the body than British Creoles. In this colony the disease is chiefly observed on the sea-coast.

In Ceylon it scarcely ever occurs except among the indigenous inhabitants of about eighty miles, or one-ninth, of the sea-coast of the island. At Point de Galle, which is the principal village embraced by the above range, the disease is extremely frequent; so much so that perhaps one-third, if not one-half, of the susceptible inhabitants are more or less afflicted with morbid enlargement of some part of the body. In other respects this is as healthy a portion of the island as any other: it is remarkably free from remittent or intermittent fever. Elephant leg seems to be endemic in the south-west coast only; and persons who are regularly affected with periodic attacks in that part of the island escape a recurrence of the paroxysms when they change their place of residence to the interior, or to another part of the coast. Cochin is considered a very healthy station for troops.

**Exciting Causes.**—The exciting causes are equally obscure. Drs. Hillary and Hendy attribute it to sudden changes of temperature; but we think without good foundation. We have known the disease affect nearly every member of a large wealthy family in Galle, the females of which, as they did not expose themselves to the sun, were not liable to a transition of temperature above ten or twelve degrees during a whole year. Dr. Hillary was of opinion that the local affection is a consequence of the precursory fever, while Dr. Hendy adopts a very different view of its pathology, and considers the fever to be a result of the topical inflammation; asserting that unless the local affection is severe, there is no fever. In cases where the internal organs are affected, and the functions impaired, constitutional excitement may thereby be excited; but it is difficult to con-

ceive that a febrile affection should be the result of the chronic enlargement of an extremity.

In some respects there is a considerable analogy between erysipelas and the disease in question. During the early stage of elephant leg the external characters of both diseases are similar. The topical affection in either disease rarely terminates in abscess. In erysipelas the inflammation is, however, commonly much more confined to the skin than in this disease; and so far as we are acquainted with the latter affection, it differs from erysipelas in regard to its periodicity, or liability to recur at short intervals, without any appreciable cause.\*

**Treatment.**—The treatment recommended by Rhazes seems to be as consonant to reason, and as consistent with the pathology of disease as any that has been suggested. It consisted of general bleeding in violent cases; emetics, laxatives, a light diet, and confinement to bed. When an inferior extremity was affected, he recommended that the limb should be rubbed with an epitheme composed chiefly of alum and vinegar, and that it should be bandaged from the toes to the knees. The natives of Ceylon seldom resort to any other remedial means in this disease, but keep their couch, or rather their mat, and drink freely of ginger tea. Dr. Musgrave asserts that, "in addition to warmth locally applied, and the ordinary purgative and febrifuge medicines, mercurial saturation of the system was the best means of securing the patient against the erratic disposition, and accordingly pyalism was the usual *companion* of convalescence from an attack of this very common complaint:" for, he adds, "I am indeed strongly disposed to believe that, since the mercurial treatment has become general, the number of cases, ending in a local or permanent deposition of lymph, has been materially lessened."—"Many individuals subject to this disease, whom I have attended for a number of years, continued to shake off each successive return without retaining the slightest trace of its having existed, or at most with a trifling induration of the inguinal glands."

In the case of a young lady, at Point de Galle, belonging to a family, several of the members of which were affected with this disease, the first attack was treated by the free application of leeches and warm fomentations. Calomel was administered so as slightly to affect the mouth. A second attack which occurred shortly afterwards was treated in the same manner. Effusion did not take place, and no return of the disease was experienced for the two years she was under observation.

When either of the great cavities was implicated, Dr. Musgrave had recourse to the lancet. Some of his medical brethren were afraid to bleed, from an "idea that the inflammation was erysipelatous." He is of opinion, however, that "the redness differs little from that of phlegmon, and suppuration under the form of genuine abscess is an extremely common occurrence; while, on the

\* Soldiers and sailors in the West Indies are frequently affected with smart attacks of an ephemeral fever, accompanied with an inflammatory state of the lymphatics of the extremities. The writer of this note has seen, in such cases, a red line from the foot to the groin, indicating the course of the lymphatic trunk.—J. F. EDITOR.

other hand, external gangrene is rarely, and vesications are almost never observed." Dr. Musgrave seems to have had extensive experience in this disease, and his plan of treatment certainly deserves a trial. It may, however, be observed that, according to his doctrines, pytialism should be the "companion" of almost every disease that occurs in the West Indies.

Authors who have described this disease, generally, if not universally, discountenance the amputation of a morbidly enlarged limb. They assert that the constitutional symptoms are apt to recur, accompanied with inflammation of some of the viscera, or of an extremity of the other side of the body. To amputate a limb while the paroxysm of fever continued to return, although at distant intervals, would, in the present state of our knowledge of this affection, be injudicious; but if the recurrence of acute symptoms had ceased for a very long period, we should be much disposed to recommend the removal of a huge, deformed, and perhaps ulcerating mass of leg or arm. The writer amputated the arm of a native of Ceylon on account of an enormously enlarged forearm and hand, similar to the case recorded in the Edinburgh Medical Journal, vol. xiii. page 54, by the late Dr. Kennedy. In this instance the man continued healthy, and no other limb became affected.

Cases have occurred, in which, in consequence of ulceration, a great quantity of a glairy fluid has been discharged, and the morbid enlargement has undergone a reduction to a very considerable extent. An artificial outlet of this kind has been tried in the scrotum, and, according to report, with advantage. Iodine, from the advantage which has been derived from it in goitre, might be tried with some prospect of benefit: the patient should always, if possible, be removed from the district where the disease is endemic.

J. SCOTT.

**ELEPHANTIASIS GRÆCORUM.** (*Tubercular Elephantiasis.*) Much confusion existed till very lately, in consequence of this term having been applied to two totally dissimilar affections.

The Arabians, we have seen, appropriated the term answering in their language to elephantiasis to an enormously swollen state of the leg; whilst the Greeks designated by it the peculiar tubercular disease which we are about to describe; the appellation being probably suggested to them either by the severity and protracted duration of the disorders, or by the coarseness and insensibility of the skin presenting some analogy to the rough hide of the elephant. The tubercular elephantiasis occasionally, also, received the name *leontiasis* from certain of the old Greek writers, in consequence of a fanciful likeness which they discovered in the stern and wrinkled visage, with its prominent brow and round eye, to that of a lion. It is the *juzam* of the older Arabians, and is still designated by a very similar name not only in Arabia, but also in Egypt, Persia, and India.

The translators of the Arabian writers entailed additional obscurity on a subject already sufficiently involved, by rendering the Arabic word which indicates this tubercular disease, by the Latin term *lepra*, which is properly applicable only to the well-known scaly affection; and the

error hence arising has received, even in our own day, still further countenance and circulation, by its adoption in the splendid work of Alibert, and in the invaluable system of Frank.

Elephantiasis of the Greeks is characterized by the existence of numerous flattened glossy tubercles, of a reddish or dark colour, varying in size from that of a split-pea to that of a large nut, and occupying usually the face, ears, or limbs. The skin is irregularly thickened and wrinkled, with a diminution of its sensibility, and a swollen appearance of the affected part. The hairs fall off from almost all parts of the body except the scalp. When a European is the subject of this frightful disease, the whole skin of the parts attacked becomes of a dirty brownish or bronzed colour, approaching to that of a mulatto. As the disease advances, some of the tubercles terminate in resolution, whilst others crack and ulcerate; these ulcerations, however, rarely become either deep or extensive, but furnish a glutinous matter which concretes into solid crusts, beneath which cicatrization usually takes place. The progress of each tubercle is quite independent of those in its neighbourhood, and is unaccompanied with pain, save in the ulcerated state.

One of the most accurate descriptions of the disease is that by Dr. Kinnis, who saw several cases of it in the Isle of France. The face was generally swollen, with large tubercles on the forehead, separated from each other by deep furrows; and smaller and more confluent ones on the cheeks, which occasionally hung down, so as to depress the angles of the mouth; the alæ of the nose were dilated, distorted, and covered with tubercles; the ears thickened, enlarged, and studded over with similar substances, and the lips penetrated by hard whitish bodies, which looked somewhat like recent cicatrices. In mulattoes the tubercles were of a light livid or copper colour, and in blacks a shade deeper than the surrounding skin. The cuticular lines and folds were every where more distinct and larger than natural. "The deeply wrinkled forehead, the bare swollen eyebrows, the heavy pendulous cheeks, the irregular expanded nose, the depressed mouth, and the thickened elongated ear-lobes, combined to render the whole visage singularly harsh and uneouth."

Similar reddish shining tubercles, but of a smaller size, usually exist within the mouth, occupying the palate, uvula, and fauces, and frequently undergo a superficial ulceration: but this is attended with so little pain that the individual is often quite unaware of their existence, even when they are in the ulcerated state. The mucous membrane of the nose is occasionally implicated, being liable to an abundant discharge of matter, to hemorrhage, and even to ulceration. The sense of smell is often totally lost, the breath becomes very fetid, and the nose may eventually be flattened from the destruction of the septum. The frontal sinuses are sometimes attacked, as is indicated by a dull pain in this region; and the voice, in almost every instance, becomes nasal and hoarse, and affords evidence of the larynx being affected. The conjunctiva of the eye occasionally suffers, and the vision becomes in some degree obscured.

The progress of the tubercles on the extremities

is altogether similar to that of those on the face; they develop themselves slowly, become inflamed, and subsequently pass into resolution or ulceration. They are most numerous on the external surfaces of the limbs, whilst the inside of the thighs and arms, and the flexures of the joints usually escape. The skin of the fore arms and of the legs is often not only tuberculated, but also scaly and scabbed, and particularly so about the knee and elbow joints.

In the case of a young man which we saw some years ago in the Hôpital St. Louis, at Paris, thin filmy scales were very evident between the tubercles. These existed chiefly on the face and arms, which were of a dirty brown colour, whilst the seat of old ulcerations was marked by still browner discolourations. There was considerable insensibility in some of the diseased patches about the wrist. The case was of old standing, and accompanied by great emaciation and debility. Ulcerations of the *alæ nasi* and throat had taken place, and the voice was much affected.

But, although a slight degree of scaliness occasionally occurs, as in the above case, it is not a characteristic feature of the disease; for it is neither an original nor a universal symptom.

The feet and hands are usually much swollen, and the motions of the joints greatly impeded by the tubercles. The nails are often coarse and furrowed. The sores are for the most part of an indolent character, with a reddish or a foul surface, little discharge, and hard and irregular edges. When the ulcerations are seated on the fingers or toes, they are apt to sink deep and terminate in gangrene; and a very serious mutilation of the extremities by the sloughing off of one or more of their phalanges is the consequence.

The tubercles very rarely make their appearance on the trunk of the body. The parts attacked become, in a great degree, benumbed, but rarely, if ever, lose their sensibility altogether.

Frank describes the disease as being accompanied with great torpor of mind and sluggishness of body, somnolence, and disturbed sleep. Mental depression amounting to extreme melancholy is the natural consequence of so hopeless a malady. Yet the general health, for a length of time, suffers infinitely less than could have been anticipated; the actions of the respiratory and digestive organs continue long unaffected, and even the cutaneous functions are still tolerably performed, as is evidenced by the abundant perspiration which can be excited by active exercise. The pulse in Dr. Kinnis's cases was generally accelerated and feeble; but others state that it remains throughout the greater part of the disease natural.

The affection has rarely been witnessed by a medical practitioner at its very commencement. In Mr. Lawrence's patient, whose case is detailed in the *Medico-Chirurgical Transactions*, it seemed to have begun by a general swelling of the head and face, and stiffness of the limbs after a wetting; on the subsidence of the swelling the tubercles began to appear on the ears, face, &c., which were at first of the same colour as the surrounding skin, but became subsequently of a reddish and sometimes of a livid hue.

The progress of the disease is very slow, and its termination, though it may be deferred for many

years, almost always fatal, the unfortunate patient being in the mean time dreadfully deformed and mutilated, and literally dying by inches. Recovery is, indeed, a very rare occurrence. In Mr. Lawrence's case the tubercles, it is true, disappeared in a great measure; but from the sudden impairment of the general health, which had been hitherto good, and from the simultaneous occurrence of thoracic symptoms, there was too much reason to apprehend that disease of the lungs had only supplanted that of the skin.

Dr. Adams has described as one of the symptoms of elephantiasis as it occurs in Madeira, a femoral tumour situated in the upper and front part of the thigh. This was absent in the case which Mr. Lawrence has so ably described, but was found by Dr. Kinnis in most of those he had an opportunity of examining—occasionally on one side only, but more frequently on both. It was placed a few inches below Poupert's ligament, and was of an oblong form, as if arising from the enlargement of two inguinal glands, and was about two or three inches in length, and moveable under the skin. At intervals of from one to four months, these swellings were liable to attacks of acute inflammation, preceded by rigor, and accompanied with febrile symptoms, which subsided after three or four days, leaving the tumour nearly as before. These swellings have, however, in one or two instances been known to proceed to suppuration.

As to the *libido inextinguibilis* which has been mentioned as one of the features of the disease, a great diversity of sentiment appears amongst the authors who have treated of it. The majority of these (Vidal and Johannis, Bancroft, Niehbulr, &c.) certainly affirm its existence, but Dr. Adams, on the contrary, asserts that the genitals become wasted; or if the disease come on before puberty, their development is interrupted, as seems to have happened in Mr. Lawrence's case, in which the scrotum was shrivelled up and the testes were unnaturally small and soft; and in the four cases which fell under Dr. Bateman's notice, both the appetite and the power were lost. Dr. Kinnis, on the other hand, who had still more extensive opportunities of observation, did not meet with this wasting of the sexual organs in a single individual, the testes in males and the breasts in females being always of their natural size; and the venereal appetite usually continued in its natural state. Menstruation is recorded to have been regular in two of the affected females, and a third had lately borne, and was still suckling, two children.

From this want of accord amongst persons who have had abundant opportunity of observing the complaint, we are at least justified in concluding that increased sexual propensities are not amongst the essential characteristics of the disease. It is possible that still more extensive inquiry may reconcile the apparent contradiction amongst authors, and show that the tendency to disease in the organs of reproduction may be variously modified by climate, or by peculiar local circumstances, which have hitherto escaped investigation. Alterations in the intensity of these feelings is not a very rare occurrence in some cutaneous affections; and it is not improbable that the extension of irritation and of morbid action to the urino-genital mucous

membrane may, in one stage of the affection, give rise to their unnatural exaltation, which may yet be followed, at a subsequent period and more advanced stage, by the very opposite state. Pathology affords many analogous instances, in which a low degree and an early stage of chronic irritation in a secreting organ, leads to its increased action, whilst a higher degree of inflammation, or a more advanced period of the disease, often interrupts its functions altogether, and terminates in the atrophy of its structure.

From a careful review of the evidence, both positive and negative, we are forced to conclude that the affection of the mammary and seminal glands, like the femoral tumour, is at most only an occasional complication.

An account of elephantiasis, in some respects differing from that of other writers, has been given by Mr. Robinson, in the tenth volume of the *Medico-Chirurgical Transactions*. According to him it is one of the commonest diseases in Hindostan; but there are two distinct varieties, and these have been usually confounded together.

In the first variety, which, from the accompanying insensibility, he proposes to call *E. anæsthetos*, (the *Barras* of Avicenna and the *Soubhary* of the natives,) there appear one or two circumscribed light-coloured patches, which are shining, wrinkled, and on a level with the surrounding skin. These occur usually on the hands and feet, and are altogether insensible. They spread slowly till the surface of the whole body may be at length implicated, and its sensibility lost. There is neither pain nor itching, and usually no swelling. After a few months the internal functions become deranged, the pulse gets very slow and heavy, "as if moving through mud;" the bowels grow costive, and there is much sluggishness of mind, and tendency to somnolence. The skin of the extremities becomes fissured and rough, and ulcers appear under the metatarsal or metacarpal joints, the integuments seeming to be simply absorbed, or sloughing off in successive layers of about half an inch in diameter, without any previous tumour, suppuration, or pain. A sanious discharge ensues, the muscle, pale and flabby, is in its turn destroyed, and joint after joint drops off. Yet the miserable sufferer clings to life, eats voraciously, and crawls about with little but his trunk remaining, till he is carried off at length by diarrhoea or dysentery. Mr. Robinson has never seen the larger joints attacked by it, the nose destroyed, or any bones affected save those of the hands and feet. The tuberculated species may occasionally supervene upon this variety, but they have no necessary or constant connection.

The second species he mentions is the tubercular elephantiasis, which commences in the face by florid semi-transparent shining patches of cuticle; the skin becomes irregularly thickened, and gives a bloated appearance to the face and ears. The arms, neck, chest, and lower part of the trunk, and the legs, become subsequently affected. The skin of the tuberculated parts is not insensible, but is affected with heat and itching. A frequent sense of weight and pain in the head, with a lethargic state of mind, ensue. The pulse

is slow and feeble, the voice hoarse, and the bones of the nose and palate often become carious. It is in this species alone, and in its commencement only, that the venereal passion is increased. In the after stages the testicles are absorbed. The fingers and toes do not, at least till a very late period, become at all numb. Bateman, though his description is in most respects accurate, has, Robinson thinks, in some points confounded these two varieties. The dropping off of the fingers and toes, the insensibility of the skin, and the extreme torpor of mind and body belong to the first; the tubercles, ulceration of the palate, and affections of the cartilages and bones of the face, together with the frequent occurrence of the oblong glandular swelling in the groin, to the second. The mudar, which is so useful in the first species, is injurious in the other; for which last arsenic is the best remedy.

Our knowledge of the morbid anatomy of elephantiasis is still very imperfect both as regards the state of the skin, and of the subcutaneous cellular membrane. The epidermis is extraordinarily thickened, and the tubercles themselves have by some been described as solid fatty tumours rooted in the true skin, whilst others speak of them as small cysts containing a reddish glutinous fluid. The cutis vera has usually been found inflamed in those spots only, when the tubercles were in a state of relaxation and suppuration. The subjacent muscles and tendons have been, in some instances, observed to be matted together. The immediate cause of death has, in most cases, appeared to be the extension of inflammation to the mucous membrane of the trachea and pharynx, and to the lungs.

As to the causes which give rise to this affection, little is with certainty known. Its origin has been ascribed to want of cleanliness and to unwholesome diet, especially the constant use of bad fish; to long-continued exposure to the heat of a tropical sun, by some writers; and to dampness of situation, or occupations requiring the frequent immersion of the limbs in cold water, by others. The number and incongruity of these supposed causes naturally dispose us to attach little credit to any of them. There is strong reason to believe that it is occasionally hereditary. A few instances favourable to the notion of its being propagated by contagion are on record; but, on the other hand, innumerable examples of individuals having been exposed for years with impunity to the closest contact with the diseased, as in the case of husbands and wives, parents and children, &c., throw much doubt on the reality of this mode of origin, and force us to attribute its occasional propagation in a family, either to hereditary predisposition, or to exposure to similar exciting causes, or both.

The disease occurs chiefly in warm climates: Arabia, India, Africa, Madeira, the Isle of France, and some of the West-India Islands, (into which last it is supposed to have been introduced by the slave-trade,) are amongst its chief localities. But northern latitudes do not enjoy a perfect exemption from its ravages, for in Norway and Iceland, elephantiasis, or at least a very similar disease, (*spedulskhed*, *radesyge*, *liktrea*,) occasion

ally prevails.—(See Hufeland's Journal for October, 1819, Henderson's Residence in Iceland, &c.)

The *pellagra* of the Milanese territory, the *rosa Asturica* of Spain; the *Crimean disease* mentioned by Pallas and Ginelin, as occurring in the neighbourhood of Kherson and of Astracan; and the *mal rouge* of Cayenne, are all closely allied to it.

Of the treatment of a disease which is almost always incurable, all that need be said may be comprised in a few words. A mild unstimulating diet, tepid baths, and soothing applications to the skin when in the ulcerated state, are points in the propriety of which all are agreed. The use of sarsaparilla and guaiacum, and of mild alterative doses of mercury with antimony, have, along with change of residence, occasionally produced a temporary amendment.

In the case at the Hôpital St. Louis, to which we have already alluded, though it was in a very advanced stage, considerable improvement was effected by the use of such simple means as the following, viz. confining the patient to a milk diet and mucilaginous drinks, along with minute doses of opium, and baths to allay irritation. This patient was under the care of M. Biett, one of the most enlightened and least exclusive practitioners in Paris; and a great variety of more energetic treatment had previously been employed with no permanent benefit.

All agree that the large employment of mercury aggravates the disease, and this, too, is often the case with arsenic, though in the form of the Asiatic pills, in which it is combined with black pepper, it enjoys a high reputation among the native physicians in the east.

Bark has been extolled by Dr. Thomas Heberden, in Madeira, and the mineral tonics have been recommended by others. Dr. Schilling, at Surinam, found much benefit from the use of the warm bath, and stimulant vapour baths, spirituous frictions, and gentle exercise; and, in truth, the more frequent occurrence of the disease on the extremities than on the trunk, renders it probable, that it is somehow connected with deficient vitality, or imperfect circulation in the skin of these parts, and justifies the employment of such measures.

From observing a temporary amelioration to take place on the occurrence of an erysipelas, and from the fact that the spontaneous subsidence of each individual tubercle is usually preceded by a degree of inflammatory action, it has been ingeniously proposed by Rayer to excite a slight degree of inflammation in the diseased skin by the use of stimulant applications, such as ammoniacal liniments, tincture of cantharides, ointments containing hydriodate of potass, &c. Should their action prove too irritating, he directs us to alternate their employment with that of the warm bath. With the view of promoting absorption, the internal use of iodine might also be tried.

W. B. JOY.

EMETICS, (ἑμετικά ἐμετικά, *emetica*; from ἔμεω, *emio*.) Emetics may be defined—substances which cause the ejection of the contents of the stomach by the mouth, independently of the stimulus of quantity, or of the influence of any

nauseous taste or flavour. When these substances, with a few exceptions, are taken into the stomach in certain quantities, they do not immediately operate, but produce an uneasy sensation attended with nausea, which increases, and terminates in vomiting. Even before vomiting commences, the influence of the emetic substance is not confined to the stomach. As soon as the nausea is felt, the countenance becomes pale; and the pulse, diminished in strength and frequency, is quick and irregular. There is occasionally great anxiety, listlessness, and depression of spirits, with a tendency to fainting; at length sweat breaks forth, and just before vomiting commences, a peculiar sensation is experienced at the clavicles. After the vomiting has begun, the face flushes, the pulse is quickened, and it remains so betwixt each effort of vomiting, which occurs several times in succession, at short intervals, before it ceases. The nausea now subsides, either at once or by degrees, leaving a transitory feeling of depression, which makes the patient indifferent to everything around him.

When emetic substances, with the few exceptions to which we have already alluded, are received into the stomach, they do not operate by any local stimulating influence on the coats of that organ; the time which elapses after they are swallowed sets aside such an opinion; and there exist other sufficient reasons for affirming that they are absorbed and carried into the circulation before vomiting is induced. When a solution of tartar emetic is injected into the jugular vein, it produces vomiting sooner than if it had been swallowed; and an experiment of M. Magendie has demonstrated that vomiting produced by an emetic substance may be stopped by pressure made upon the medulla oblongata. Now the inference that may be drawn from this fact is, that the action of emetics is not owing to any local stimulus on the nerves of the stomach, but to the action of the emetic substance, after being absorbed into the circulation, as a direct stimulus to the origin of the nerves, whereby contractions of the stomach, and the actions of the other muscles concerned in the act of vomiting, are induced. These nerves comprehend a branch of the eighth pair, the intercostal, and the phrenic nerves.

It may be inquired—what is the nature of the irritation which excites vomiting? Does it depend on the physical character of the particles of the substance employed? or is it the result of some chemical or electro-chemical change? These are queries which cannot be satisfactorily answered: all that can be said is, that there is, probably, something connected with the substances which cause vomiting, which has the power of irritating a particular set of nerves only: for were this not the case, why should tartar emetic, when injected into the jugular vein, excite vomiting?

Vomiting may be produced by a variety of causes, either connected directly with the stomach itself, or indirectly, by sympathy with it through the medium of the nervous system.

1. Vomiting may be directly induced by food undergoing changes inconsistent with healthy digestion; by mechanical irritants lodging in the stomach; by tumours pressing on the pylorus; by inverted actions of the intestinal canal, forcing

the contents of the duodenum, particularly the bile discharged into it from the biliary duct, into the stomach; by chemical acids and other poisons, or emetic substances taken into it; by any the mildest substances, when inflammation of its coats, or ulceration, augments its nervous irritability.

2. Vomiting may be indirectly induced by strangulations of the intestinal canal; by the irritation arising from biliary or renal calculi impacted in the excretory ducts of the liver or of the kidneys; by titillation of the fauces; by inflammation of certain portions of the contents of the cranium, for example, of the arachnoid membrane covering the base of the brain; by repelled cutaneous eruptions; by emetic substances injected into the veins; by sailing, swinging, riding in a carriage, and other movements of the body; by pregnancy; by the influence of certain odours; and by mental impressions. Whichever of these causes produces vomiting, a specific action of the stomach, and the consent of certain muscles of the thorax and the abdomen are, in every instance, necessary to produce the effect: thence the question, in what manner is vomiting effected? In replying to this query, let us first enquire what opinions have been advanced regarding it by others.

M. Chirac (*Histoire de l'Académie des Sciences*, 1686) first suggested the opinion that the stomach is passive during vomiting, which he contends is effected solely by the action of the diaphragm and the abdominal muscles; an opinion afterwards adopted by Duverney, Bayle, and John Hunter. M. Litre denied the influence of the abdominal muscles, and maintained that the diaphragm is the chief agent in producing vomiting. Lieutaud and Haller supported the idea that the stomach is the real agent; the former founding his opinion on having observed, in a patient who could not be made to vomit by the most powerful emetics, that the stomach was greatly distended and insensible. Sir Charles Bell (*Anatomy of the Human Body*, vol. iv. p. 54) appears to hold nearly similar opinions to those of Lieutaud upon this subject. "That vomiting," says he "may be produced by the inverted motion of the stomach and diaphragm alone, is apparent from experiments upon living animals, where the abdominal muscles are laid open, and from cases in which the stomach has rested in the thorax, and yet been excited to active vomiting." He also states that the walls of a stomach in his possession "had become so thick that they could no longer suffer contraction by the muscular fibres; the consequence of which was, that although the inner coat of the stomach was in a raw and ulcerated state, there was no vomiting." Sir Charles, however, modifies this opinion by remarking "that, when the stomach is excited to vomiting, there is consent of the abdominal muscles, by which they are brought into violent spasmodic action; not alternating in their action, as in the motion of respiration, but acting synchronously, so as greatly to assist in compressing the stomach; but," he adds, "at the same time, the action of these muscles, however forcible their contraction, cannot alone cause vomiting; nor has this action any tendency to produce such an effect on other occa-

sions, in which the utmost contraction of the diaphragm and abdominal muscles is required to the compression of the viscera."

M. Magendie, in an able memoir published in 1813, supports the opinion of Chirac. (See also *Précis Élémentaire de Physiologie*, vol. ii. p. 140.) In one of his experiments, he drew the stomach through an opening of the abdomen, thus freeing it from the influence of the diaphragm and abdominal muscles, and he found that vomiting could not be excited. He also ascertained, that if all the abdominal muscles be removed, leaving only the linea alba, vomiting still occurs from the stomach being pressed, as he supposes, between that part and the diaphragm. In another experiment he states that he substituted a pig's bladder for the stomach, and nevertheless, vomiting took place! He found that the division of the phrenic nerve weakens the action of vomiting, but does not altogether prevent it.

These experiments prove—1. that the influence of the nervous system is essential to the production of vomiting; 2. that the abdominal muscles greatly influence the ejection of the contents of the stomach. But they do not satisfactorily explain the action of the diaphragm, nor the part which the œsophagus bears in the operation of vomiting. Dr. Richard Harrison, in his *Gulstonian Lecture*, adopts the opinions of Chirac and Magendie, as far as regards the action of the diaphragm and the abdominal muscles; but he adds to this call upon the expiratory muscles through the agency of the brain, and their consequent action, the contraction of the stomach itself. There can be no doubt of the agency of the nervous system in this operation; the only question is, whether the excitement be first exerted on the extremities of the nerves of the stomach itself, from which the impression is communicated to the brain by sympathy, and the auxiliary muscles be thus called into action: or whether, as the writer of this article imagines to be the case, the impression is made upon the spinal marrow from the absorption of the emetic substances, and through the influence of the motor nerves to the respiratory muscles, so that all the machinery concerned in the operation is excited into simultaneous action.

Dr. Marshall Hall has endeavoured to prove that Magendie's assertions respecting the influence of the diaphragm are incorrect, and that the act of vomiting is in fact a forcible expiratory effort. He contends that, if the diaphragm contracted, as Magendie affirms, the act of vomiting would be attended by inspiration; that the glottis, in such a case, would necessarily be open, and that the fluids ejected from the stomach would be drawn into the larynx, and induce great irritation there; an event which does not occur in vomiting. On the contrary, as M. Magendie admits, although he contends for the agency of the diaphragm, the larynx is accurately closed at the instant that the vomited matter is passing through the pharynx. Dr. Hall's explanation of the mechanism of vomiting is this: "the contents of the thorax and abdomen are subjected to sudden and almost spasmodic contraction of all the muscles of expiration, the larynx being closed so that no air can escape from the chest, and the two cavities being made

one by the floating or inert condition of the diaphragm." The mere mechanism of vomiting, therefore, according to Dr. Hall, "differs little from that of coughing, by which indeed the contents of the stomach are frequently expelled: the larynx in the former is, however, permanently, in the latter, only momentarily closed; and there is doubtless a different condition of the cardiac orifice and of the œsophagus." In order to confirm his opinion, Dr. Hall made an opening into the trachea of a dog, which was excited to vomit by subsulphate of mercury; during the act of vomiting, the air from the lungs was forcibly driven through the artificial opening. Dr. Hall, in his explanation, admits the influence of the œsophagus, and adds, "it is plain that the cardiac orifice must be freely opened; for mere pressure upon the viscera of the abdomen will not, in ordinary circumstances, evacuate the contents of the stomach. To effect this open state of the cardiac orifice, it is probably necessary that the diaphragm should, indeed, be in a relaxed rather than in a contracted state." There is much ingenuity and considerable truth in this theory; but it does not wholly explain the operation of vomiting. The following opinion of the writer of this article may be regarded as a modification of that of Dr. Hall.

He admits that it is true that the glottis is closed, and that a powerful effort is made as if of expiration; but this effort is not altogether that of expiration; for, whilst there is a powerful and sudden contraction of the abdominal muscles, forcing up the whole contents of the abdomen towards the thorax, the diaphragm is fixed, owing to the closing of the larynx, and the retention of the quantity of air which the lungs contained at the commencement of the effort. The diaphragm is thus prevented from ascending into the chest; and the pharynx being drawn up as in the act of deglutition, opens the cardiac orifice of the stomach, and forms with this viscus one continuous cavity. This open state of the cardiac orifice of the stomach, forming one continuous cavity of the stomach and pharynx, explains an observation of M. Magendie, that "during the state of nausea which preceded vomiting, in some of his experiments, air was drawn into the stomach." Now, if it be true that the cardiac orifice of the stomach is open, and the mouth, the œsophagus, and the stomach be one continuous cavity, it is evident that the external air, which is heavier than the air and vapour contained in the stomach, will necessarily be forced into this organ by its mere gravity, as it would be into an ordinary receiver containing vapour and little or no air. In this state, by the sudden compression of the stomach by the abdominal muscles drawn forcibly and suddenly inwards, the diaphragm being fixed, the contents of the stomach must be directed upwards, with a degree of force commensurate to the suddenness of the pressure upon its walls; and consequently they are thus ejected by the mouth. If this description be correct, it is evident that the act of vomiting is the result of the simultaneous action of all the muscles of respiration, at a moment when the glottis is shut, and offers resistance to the ascent of the diaphragm. Dr. M. Hall is correct in describing it as an expiratory effort; but this

effort alone would not effect vomiting, were there not the resistance which has been described opposed to it. The stomach, therefore, is in every respect passive; and it is not obvious that contraction of that organ forms any part of the process of vomiting; it is rather in a state of relaxation than of contraction. Thus, if a bag half filled with fluid, with an open tube rising from it, were suddenly struck or compressed, the fluid would be ejected through the tube; but if, at the same time, the bag was also contracting its general capacity, the impulse of the compressing force would be necessarily diminished, and the impetus of the ejection of the fluid considerably weakened.

Such is the view of this operation taken by the writer of this article: but in whatever manner it is accomplished, there can be only one opinion respecting the share which the nervous system has in the operation. "This act, (vomiting,) will not take place," justly remarks Dr. Paris, "however forcibly the stomach may be goaded by emetics, where the energy of the nervous system is suspended, as in cases of profound intoxication, or in violent wounds or contusions of the head; while, if the brain be only partially influenced, as by incipient intoxication, or by a less violent blow upon the head, its irritability is increased instead of being paralysed, and vomiting under such circumstances is excited by the slightest causes." (*Pharmacologia*.)

The first effect of the influence of an emetic on the system is the production of nausea, and a consequent diminution of general excitement: this is followed by the ejection of the contents of the stomach, and an alteration in the condition of its secreted fluids: thus, for example, in dyspepsia not only do emetics eject any superabundant acid contained in the stomach; but they also so influence the functions of the secreting follicles, that for some time all acid totally disappears. Along with the contents of the stomach, bile is also generally ejected, owing to the compression of the liver and the gall-bladder forcing a large quantity of this secreted fluid into the duodenum and the stomach. In the act of vomiting, also, all the abdominal viscera being compressed, the blood is propelled more forcibly through their vessels; thence a change is effected on the intestinal secretions, and on those of the pancreas and the spleen: even the kidneys are affected, and the quantity of urine is considerably increased. The pulmonary system is also influenced, a freer circulation of the blood through the lungs is promoted, and the action of the secreting and exhalent vessels is augmented. But, besides these effects of emetics on the particular organs, the result of their influence on the general system is the equable distribution of the blood to every part of the body; and the consequent removal of local determinations and congestions. How far these effects depend in part upon the absorption of the emetic substance is yet to be ascertained.

Emetics operate as evacuants in other respects than by emptying the stomach: they induce diaphoresis, and by stimulating the capillary system, and thereby checking the effusion of serous fluids into the cavities of the body, enable the absorbents to carry off any fluid already accumulated there: hence their utility in dropsical affections. By the

nausea, also, which attends their operation, abating the force of the circulation, they have sometimes proved useful in active hemorrhages.

Although all the substances classed as emetics accord in producing more or less nausea and vomiting, yet they differ in some circumstances.

1. *Emetics differ in the time required for producing their effects.*—The sulphates of zinc and of copper operate the quickest of all the emetic substances in common use, exciting vomiting almost as soon as they are swallowed. Tartar emetic, and the other active antimonial preparations, and subsulphate of mercury, operate quickly also, but less so than the salts of zinc and of copper; whilst all the vegetable emetics are still more tardy in producing vomiting. This diversity in point of time has not been satisfactorily explained: it has been supposed to depend on the solubility of the emetic substance in the gastric juice, and its consequent application to the extremities of the nerves of the stomach being thus more or less facilitated. But, independently of the fact that all emetics, with the exception of the few which operate by their direct influence on the nerves of the stomach, are absorbed before they produce their effects, there is no evidence of this action of the gastric juice; and substances already in a state of solution are influenced by the circumstances, whatever these may be, which produce this diversity. Two substances held in solution in the same solvent, and conveyed into the stomach under the same circumstances, differ considerably in the time which elapses before they operate. Thus a solution of tartar-emetic in wine operates sooner than a vinous solution of ipecacuanha; although, were both these substances in the solid state, and were the action of the gastric juice on them requisite for their operation, it is probable that the vegetable substance would be the most readily dissolved, and consequently operate most quickly; but the reverse is the case. It is probable that the diversity depends on the more rapid absorption of the antimonial salt than that of the emetina, the active principle of the ipecacuanha, after both have passed the pylorus. The time required for the operation of different emetics should be familiar to the physician, as much of the benefit to be expected from this order of remedies sometimes depends upon this circumstance.

2. *Emetics differ in the degree and the severity of their effects.*—The saline emetics in general operate more violently than the vegetable emetics; but the latter cause a more severe and longer-continued nausea. It is not easy to account for these effects, unless we admit that, although the first impression of the saline emetic on the nervous system be the most energetic, yet, that the saline substance is more readily decomposed, or thrown out of the system, than the vegetable.

It is of much importance, in a practical point of view, to attend to the degree of energy of operation of different emetics, and to avoid any risk connected with their violent action. Emetics do not operate with much energy on persons of torpid habits; larger doses are required than in ordinary cases; and, not unfrequently, vomiting cannot be excited by any dose. When this is the case, emetics cause great anxiety and uneasiness. Persons of a sanguine habit are more easily affected

by emetics than those of a melancholic women than men; children than adults: thence experience has informed us that, in febrile affections, vomiting is a common symptom in such persons. It is of some importance to know how to anticipate the degree of difficulty or facility with which different persons can be excited to vomit, seeing that not only those who are not easily excited suffer from pain and anxiety, but those who are very easily affected are apt to be injured by even the ordinary dose of an emetic.

Emetics are contra-indicated in some conditions of the system. In all cases in which the phlogistic diathesis prevails, they ought not to be administered until after bloodletting and purging have been employed. They have, nevertheless, been found very beneficial in some inflammatory affections. In croup they are supposed to be specially indicated: Dr. Crawford, and many subsequent writers on that disease, recommend them to be administered in the earliest stage of it: others, however, urge the propriety of waiting until the inflammatory action be at least mitigated by the use of the lancet, calomel, and purgatives. In those cases in which we have seen them employed in the commencement of the disease, much less assistance has been required from bloodletting than when they have not been given. We must admit, however, that when the inflammatory symptoms run high, they are at least of doubtful efficacy. In pneumonic affections, also, if the state of the bronchial cavities require the influence of an emetic to aid expectoration, they ought not to be employed until after the excitement has been reduced by the proper use of the lancet. As pressure is necessarily applied to the descending aorta during the action of vomiting, there is a temporary interruption to the pulmonary circulation, and the blood is returned with difficulty from the head; consequently vomiting should not be excited in states of the habit predisposing to apoplexy. From the compression, also, of the abdominal viscera, the administration of emetics requires caution in those afflicted with hernia and prolapsus of the anus or of the uterus; nor are they always admissible in the advanced stage of pregnancy. The spontaneous vomitings which attend the early stage of pregnancy are sufficient guarantees of their safety at that period. In diseases of debility, and in weak and delicate subjects, emetics, especially those which nauseate, should be carefully avoided. Experience has also proved that the frequent employment of emetics is injurious, producing general debility, and such an irritable state of stomach that it is excited to vomiting by the most trifling causes, even by changes in the nature of the food; indeed no means are so likely to induce dyspepsia as the custom of taking frequent emetics.\*

\* This remark is, apparently, at variance with the custom of the Romans. Emetics were daily taken to enable them to relish the enjoyments of the table; and so far did the Romans carry this custom, that they sometimes excited vomiting to eject from the stomach what they had eaten in one course, that they might be the more capable of enjoying what was to follow. According to Seneca, "they vomited that they might eat, and ate that they might vomit." They employed emetics before meals, that they might be able to eat more plentifully; and they often concluded a feast with an emetic, to prevent the consequences of gluttony. In one of Cicero's epistles to Atticus, he describes a visit which re-

With respect to the period of the administering emetics, much must depend on the circumstances of the case which demand their employment.\* If there be no immediate urgency, the evening is the best time; for as the body is always more or less exhausted by the operation of an emetic, the tendency to sleep which supervenes can then be readily indulged. Attention to the period for administering emetics is particularly requisite in febrile affections. Thus when they are necessary in continued fever, the time of day for administering them with most advantage must not be overlooked. In almost every continued fever there is a mid-day and an evening exacerbation. These are not always very obvious: the evening one, however, is the most so; and its approach is marked by increase of pulse, thirst, headache and dry hot skin. It is immediately prior to this accession that emetics will be found most useful, sometimes checking it altogether, at other times at least diminishing its violence.

In reference to the operation of emetics, we may remark that the dose of the emetic substance should be sufficient to produce full vomiting, otherwise nausea and restlessness, instead of vomiting, will follow the administration of the medicine. It is the custom to order warm water to be freely drunk during the operation of an emetic. This certainly promotes its action if the fluid be taken after each time of vomiting; but it is requisite to be cautious that too much is not taken at once. The stomach, when oppressed with water, does not yield to the action of the muscles which are excited to produce vomiting, thence it is in danger of laceration. There are several instances on record of this having occurred; but it may be questioned whether rupture ever happened, unless the organ was previously diseased? The quantity of fluid for an adult should not exceed two-thirds of a pint at a draught; it should be tepid, and, if the stomach be weak, some bitter infusion, as, for instance, that of camomile flowers, or a few drops of liquor ammonia in the water, should be employed to aid the action of the emetic. If the vomiting be severe and long-continued, it may be checked by solutions of neutral salts; sulphate of magnesia, for example, or citrate of potassa, formed with the carbonate of potassa and fresh lemon-juice, given in a state of effervescence; or a teaspoonful of magnesia may be given in a glass of sherry; or solid opium or hydrocyanic acid may be administered in small doses.†

All substances employed to excite vomiting may be arranged in two classes—*direct* and *indirect* emetics.

**I. Direct Emetics** are substances which cause vomiting by an immediate impression on the nerves of the stomach. It may be asked, how

made to Cesar, at his villa near Rome; and states that his distinguished host paid him the compliment of taking an emetic before dinner, when he understood that Cicero intended to spend the day with him.

\* Some of the old writers, Stoll in particular, regard the period of the day as a matter of indifference. Rat. Med. 11.

† Many other means may be employed to check vomiting; as, for instance, the administration of subnitrate of bismuth, infusion of calumba, strong coffee, tincture of capsicum diluted with water, in that induced by pregnancy and sailing;—a large dose of calomel, and dry cupping on the epigastrium.

can this take place, if the stomach be a passive agent in the act of vomiting? We reply, that by the term passive agent we do not mean to assert that the stomach is insensible to the stimulus of all emetic substances; on the contrary, all irritants, whether chemical or mechanical, are capable of stimulating the stomach to vomiting; but, nevertheless, in this operation, the stomach is not the active agent. This seeming inconsistency may be thus explained. When the stomach is in the performance of its natural function, the digested food is pushed forward to the pyloric orifice; but if the chymification be not complete, it is again thrown back into the fundus, and occasionally into the pharynx, producing eructation; a circumstance, however, which occurs only when the secreted juices of the stomach are in a morbid state; and, under this condition, the ejection resembles in every thing but degree that produced by emetics. In a similar manner, when a large dose of sulphate of zinc, for instance, is swallowed, its immediate application to the nerves of the fundus of the stomach produces a spasmodic contraction there, which throws the whole contents of the viscus mixed with the sulphate upon the pylorus; but these are as rapidly returned, even before the relaxation which must follow the spasmodic contraction have taken place; and by this means, the emetic substance being applied to the nerves of the cardiac portion of the stomach, the muscles and every other part necessary for effecting vomiting are simultaneously called into operation, and vomiting takes place. This is the opinion of the writer of this article, and he conceives that it is the only theory capable of explaining the immediate emetic influence of sulphate of zinc, sulphate or acetate of copper, and carbonate of ammonia. These substances, when taken into the stomach, first hasten, in a spasmodic degree, that action of the organ which carries the food forward to the pylorus; and there acting *contra naturam*, instead of opening the pyloric orifice, they are thrown back upon the cardiac portion of the stomach, the nerves of which being suddenly impressed, call into play all those sympathies which operate to produce the action of vomiting. If this theory be admitted, it may be applied to explain not only the vomiting caused by powerful irritants when swallowed, but those also which occur in cancerous affections of the pylorus, and in the early stages of pregnancy. Thus, in cancer of the pylorus, when food is taken into the stomach, no vomiting occurs until it is pushed forward to the pylorus, which, being morbidly excitable, throws back the food mixed with acrid matters, the result of the disease, and these acting on the sentient extremities of the eighth pair of nerves spread on the cardiac portion of the stomach, the muscles of the abdomen and those of respiration are instantly called into action to relieve the stomach of the offending matter. In pregnancy, again, the sympathy between the stomach and uterus is such, that the disturbance of the former is in the direct ratio of the energy of the latter; digestion, therefore, becomes depraved, the chyme is imperfectly formed, and, mixed with the acrid secretion, is thrown back from the pylorus, and applied to the cardiac nerves, and vomiting is necessarily excited.

Substances which act in the manner just described are those which constitute *direct emetics*. Their operation is preceded by no nausea, neither is any left behind after it is completed. Emetics of this division, therefore, are adapted for producing full and immediate vomiting, in those conditions of the habit in which the exhaustion caused by nausea would be injurious, but in which it is nevertheless necessary to unload the stomach. They are also the most useful in cases of poisoning, not only on account of the rapidity of their operation, but from their action not being followed by absorption, which, in such instances, would prove highly prejudicial. Direct emetics are few in number, and are all inorganic substances.

1. *Ammonia*. If the official solution of *ammonia*, to the extent of half a fluidrachm, be swallowed in a cupful of cold water, and the same quantity of tepid water be taken immediately afterwards, it excites instant vomiting. But as untoward circumstances have occasionally followed the administration of the solution of pure ammonia, it is rarely employed as an emetic; the carbonate, in doses of from  $\mathfrak{zss}$  to  $\mathfrak{zj}$  being given in its stead. It has been found serviceable in those cases of chronic catarrh, in greatly debilitated habits, in which expectorants cannot with propriety be administered. In such a state of the system, the act of vomiting, induced by the ammonia, aids in unloading the bronchial tubes, whilst, at the same time, a salutary stimulus is given to the nervous system; and the expectoration, which in general is suspended in such cases, is again brought on. When administered in larger doses, ammonia operates as an irritant poison, and requires the immediate administration of vinegar to neutralize and obtund its acrimony. (See *Toxicology*.)

2. *Sulphate of zinc*. This is a more safe direct emetic than ammonia, and equally powerful in its effects. It excites no nausea, and operates as soon as it enters the stomach, producing a single but copious ejection: it is, therefore, well adapted for cases of poisoning, and to excite vomiting in the commencement of the paroxysm of ague, when we are desirous of breaking the morbid association which keeps up the disease, by giving such an impulse to the system as will propel the blood to the surface, and equalize the circulation. In cynanche tonsillaris, when abscess forms in a situation which cannot be readily reached by the knife, and yet does not seem disposed to break, as the object of prescribing an emetic is merely to burst the abscess, the sulphate of zinc is to be preferred to any other substance. The dose of the sulphate to produce full vomiting is from  $\mathfrak{zj}$  to  $\mathfrak{zss}$ . If an overdose have been taken, the best antidotes are cretaceous mixtures, milk, and albumen, after the use of the stomach pump.

3. *Salts of copper*. Both sulphate and acetate of copper operate as powerful direct emetics. They have been employed in the incipient stage of phthisis; and it is a curious fact that in this disease the sulphate will sometimes lie in the stomach for upwards of half an hour without producing vomiting, and then operate at once, and as forcibly as when it acts in the usual manner. We

may here be permitted to remark, that emetics have been regarded as specifics, and have been prescribed in every stage of this disease. "It is remarkable," says Dr. Young, "that a very great majority of the cures of consumption, which are related by different authors, have either been performed by emetics or by decidedly nauseating remedies." (Young's Practical and Historical Treatise of Consumptive Diseases, &c. p. 65.) They were employed in this disease by Hippocrates, whose emetic was a compound of honey, vinegar, and water; (Hippocrates on Int. Aff.) and by Galen, who followed the example set by the father of physic. Bennett, Morton, Etmuller, Wainwright, Russell, Bryan Robinson, Marryat, Donald Monro, Macbride, and many other equally distinguished physicians speak also favourably of their effects. The confidence of Dr. Reid and Dr. Simmons in the use of emetics in phthisis was unbounded. Dr. Mackittrick Adair held almost as sanguine an opinion of their beneficial influence as Dr. Reid: he gave first a pint of warm water, then a grain of sulphate of copper with a drop of dilute sulphuric acid in half an ounce of water every other evening for three days; then every morning. (Duncan's Commentaries, 1791; p. 473.) Notwithstanding these strong testimonies, truth obliges us to state, that the method of treating phthisis with emetics has not succeeded in our hands, nor in those of many of the most distinguished men who, at different periods, have adorned the profession. If emetics, however, be employed, those which operate directly, the sulphates of zinc and of copper, should be preferred. The dose of the sulphate of copper is from ten to fifteen grains dissolved in three ounces of water. In cases where it has been overdosed, the best antidotes, after the use of the stomach-pump, are ferrocyanate of potassa, milk and albumen.

II. *Indirect Emetics* are obtained both from the organic and inorganic kingdoms of nature. Indeed, whatever disturbs the energy of the brain to a degree sufficient to affect the stomach by nervous sympathy, and to call into action the muscles necessary to establish the act of vomiting, may be regarded as an indirect emetic. Thus the mechanical irritation of the uvula and velum of the palate with a feather or with the finger; the motion of a carriage, swinging, whirling, sailing, and many narcotics, produce nausea and vomiting; and the same effects result from inhaling some gases.

Among the organic substances which operate as indirect emetics are some varieties of acrid oil, in combination with resin and other principles, as found in the cotyledons of *sinapis nigra*, the flowers of *anthemis nobilis*, and the leaves of *asarum Europæum*.

1. *Mustard*. A table-spoonful of flour of mustard mixed in water forms a ready and useful emetic, in cases which admit of stimulants: it operates quickly, and with less nausea than the direct emetics. This dose is rather large if the flour of mustard be genuine; but that usually sold in the shops contains, according to Dr. Paris, one-sixth part only of genuine mustard. Emetics of flour of mustard are useful in cases of intoxication threatening apoplexy, as the stimulant pro

perty of the mustard proves beneficial after its emetic operation is over. In the atonic form of gout, also, in which no irritation is more hurtful than that arising from crude undigested matters in the stomach, a mustard emetic may prove highly beneficial, or at least the substance employed to excite vomiting, in such a case, should be of a warm stimulant kind, the operation of which is not followed by debility. For the same reason, no emetic is so well suited for cases of malignant cholera as mustard.

2. *Camomile Flowers*. A strong tepid infusion of these flowers is powerfully emetic, when administered in doses of from  $\text{f}\frac{3}{4}$ iii to  $\text{f}\frac{3}{4}$ iv; and a weaker infusion is well adapted for promoting the action of other emetics, when the stomach is weak and likely to be oppressed by the use of tepid water.

2. *Asarabaca*. This plant owes its emetic property to a combination of acrid oil and cytissina.\* It is very seldom employed, as it loses much of its emetic power by drying and keeping.

4. *Emetina* [*Emetia*]. A more common indirect emetic than either of the three substances already mentioned is *emetina*, as contained in the roots of *ipecacuanha*, (*cephaelis ipecacuanha*.)† This principle operates more quickly as an emetic than the root which yields it, and its action is followed by sweating and a tendency to sleep. It has not been much employed in this country, but the French physicians prefer it to *ipecacuanha*. It is ordered in a solution of four or five grains in six fluidounces of water, of which two fluidounces are ordered to be taken every half hour until full vomiting is procured. That it operates on the nerves through the medium of absorption has been demonstrated by injecting a minute portion of it into the jugular veins, the cavity of the pleura, the tissue of the muscles, and the anus of a dog; in all of which modes of applying it, vomiting is produced. If it be over-dosed, dangerous, sometimes fatal effects ensue: when the latter occur, it excites inflammation of the mucous membrane of the alimentary canal, and the lungs are found gorged with blood, and approaching to hepatization. The best antidote is infusion of

\* This peculiar principle received its name from having been first obtained from the seeds of the cytissus *laburnum* by MM. Chevallier and Lassaigue. In a separate state it is of a yellow colour, has a nauseous bitter taste, attracts moisture from the air, dissolves readily in water, less so in alcohol, and is totally insoluble in ether. It is better known from its negative than its positive qualities, as none of the re-agents which usually precipitate bitter vegetable infusions make the least change in it; nor does it display either acid or alkaline properties.

† *Emetina* is procured from *ipecacuanha* by treating the powdered root with cold distilled water until it ceases to take up any more soluble matter. This watery infusion is then to be concentrated by evaporation in a water bath; subcarbonate of magnesia added to it in excess, and the evaporation continues to dryness; after which it is to be treated with strong alcohol, and the extract thus procured again treated with water, and evaporated to dryness. In its pure state *emetina* is white, pulverulent, unalterable in the air, scarcely soluble in cold water, soluble in hot water and in alcohol, but not in ether. Its taste is slightly bitter, and it displays alkaline properties. It is usually, however, procured in the form of brown scales, semi-transparent, with an odour resembling caramel, and a bitter, slightly acid taste. It is a compound of carbon, hydrogen, oxygen, and nitrogen. Gallic acid, and infusion or tincture of galls precipitate from its solutions in an insoluble form; and it is also thrown down by tincture of iodine, subacetate of lead, bichloride of mercury, and muriate of tin. When it is separated from the *ipecacuanha*, what remains is inert. It was discovered by M. Pelletier in 1817.

galls, which, by forming an insoluble precipitate with the *emetina*, neutralizes and renders it inert.

5. *Ipecacuanha root*, radix *cephaelis ipecacuanha*, which owes its emetic properties to the principle just described, has been known in Europe as an emetic since the middle of the seventeenth century.‡ It is administered in the form of powder, infusion in water, and solution in wine. The powder is the cortical part of the root, the central or ligneous part being inert: it should be of a bright grey colour, have a nauseating disagreeable odour, and a bitter acrid taste which remains in the throat.§ In doses of from  $\text{ʒi}$  to  $\text{ʒss}$  it produces full vomiting. If  $\text{ʒss}$  of the powder be triturated with  $\text{f}\frac{3}{4}$ vi of water, and  $\text{f}\frac{3}{4}$ ii of the solution administered at the distance of half an hour, full vomiting generally follows the second dose. The vinous infusion is chiefly ordered for children in doses of  $\text{f}\frac{3}{4}$ ii, repeated every fifteen minutes until vomiting be produced.

When *ipecacuanha* in any form is taken into the stomach, its first effect is on the mucous membrane, as a local irritant: it is, however, partially digested in the stomach, and the *emetina* thus separated is absorbed and produces that simultaneous action of the muscles of the abdomen, the thorax, and the diaphragm, which constitutes vomiting. But, sometimes, in the largest doses, it fails to produce this effect; a circumstance, which, if the drug be genuine, can only be attributed to idiosyncrasy. In administering *ipecacuanha*, or its active principle, as an emetic, it may be given with the intention of either simply unloading the stomach, or of acting sympathetically on more distant organs after it has performed its emetic effect. When prescribed with the first intention, it frequently operates also on the bowels, owing to some of it being forced beyond the pylorus in the first effort of vomiting; and on this account, when added to jalap, the purgative properties of this drug are much augmented. When it is desirable to extend its action after vomiting, this part of its operation should be less aided with tepid water than when vomiting only is required; the result is a powerful determination to the surface and copious perspiration, from the continuation of nausea after its emetic effect has ceased. The question has frequently been discussed, whether *ipecacuanha* and tartar-emetic may be indifferently employed as an emetic? The answer is not difficult. In choosing between these emetic substances, we must be guided by the condition of the system, and the nature of the disease, as well as the intention for which the emetic is prescribed. In intermittents, if the frame of the patient be delicate, *ipecacuanha* is to be preferred; if it be robust, capable of bearing full vomiting with impunity, and without suffering from the subsequent debilitating effects of profuse sweating, the antimonial preparations will be found most useful. In continued fever, in selecting an emetic we must not only prefer that which will produce full vomiting, but which will excite also that state of the surface which may

‡ The name of the root is a compound of two Peruvian words, *ipe* signifying root, and *Cuanha* the name of the place where it was first found.

§ Owing to a peculiar idiosyncrasy, some persons are affected with severe dyspnoea by the odour of *ipecacuanha*. (See *ASTHMA*.)

act as a crisis; consequently the tartrate of antimony and potassa is preferable to ipecacuanha. The influence of nausea in checking hemorrhages has been well established; but the superiority of ipecacuanha over all other emetics in those connected with the uterus, has only lately been established by the experiments of M. Caffin, (*Journal Général de Médecine*, vol. lxix.) and Dr. Osborne, of Dublin. (*Observ. on the Employment of Ipecac. in Menorrhagia.*) The latter found that in doses of a scruple taken in the evening, and followed by an acidulated saline purgative next morning, the discharge in menorrhagia ceased in twenty-four hours; and when it returned after a short interval, the repetition, once or twice, of the ipecacuanha emetic never failed to render the cure permanent. Dr. Osborne's experiments were conducted in Sir P. Dun's Hospital: in several of the numerous cases treated in this manner, the ipecacuanha arrested the discharge after tartar-emetic had produced no beneficial effect: and its influence was not modified either by a full pulse, with much excitement, or in a greatly weakened state of the system. In dysentery the superiority of ipecacuanha, when full vomiting is required, was determined by a set of experiments made by Sir George Baker. (*Trans. of the Royal College of Physicians of London*, vol. ii.) Finally, ipecacuanha is preferable in every instance in which the powers of the stomach require to be maintained, and yet vomiting is requisite; and in cases in which a chronic diarrhœa exists, there can be one opinion only as to its superiority over tartar-emetic.

Although the usual dose of ipecacuanha is from  $\mathfrak{z}\text{i}$  to  $\mathfrak{z}\text{ss}$ , to promote full vomiting, yet this must vary considerably in reference to sex and temperament. The dose for a young infant is gr. i; for a child of from six to ten years of age, grs. x; and for the youth of either sex under twenty, from gr. xiv. to  $\mathfrak{z}\text{i}$ .

With respect to the propriety of substituting emetina for ipecacuanha, some advantages might result from doing so; its effects, as an emetic for instance, are more certain, and its use is generally followed by sweating and a tendency to sleep. The dose of the emetina is small, not exceeding gr. v. for an adult; and as it is very soluble in water, it can be more readily administered in divided doses than ipecacuanha. Besides, the powder of ipecacuanha loses much of its activity when kept for many months, whereas emetina is not at all altered by keeping.

6. *Squill*, *scilla maritima*.—The bulb of the squill, when properly dried, possesses considerable emetic powers, which are said to be attributable to a peculiar principle named *scillitina*;\* but this is a compound substance, containing, besides the active principle of the squill, sugar, and traces of citrate of lime. Ether, when digested on squill, and evaporated afterwards on water, leaves on the surface a thin pellicle, intensely bitter, whilst a soluble matter mingles with the water: this pellicle

is the real active principle of squill. Squill is seldom employed as an emetic; but in cases where its emetic influence is no objection and does not interfere with its expectorant powers, as in whooping-cough, croup, and some other pulmonary diseases, it is found useful. When emetics are thought to be serviceable in ascites and anasarca, squill has been supposed to be particularly indicated, but it is in no respect superior to tartar-emetic in such cases. It is given in the form of powder, in doses of from grs. iii. to gr. xii; or, in that of tincture, from  $m\text{.xxx.}$  to  $f\text{.zj.}$ , repeated at intervals. When overdosed it operates as a narcotic-acid poison, causing violent vomitings, diarrhœa, tormina, bloody urine, tetanus, and a cuticular eruption resembling urticaria: in some habits these effects result even after a small dose of the medicine.

7. *Tobacco*, *folia nicotianæ tabaci*, displays powerful emetic properties, whether it be taken into the stomach, inserted into the rectum, or applied to the surface of the body; but its operation is too difficult to control to permit it to be prescribed, under any circumstances, as an emetic. It is mentioned merely because it has lately been recommended as a remedy in dropsy. In the event of its use producing poisonous effects, it is proper to know that infusion or tincture of galls renders the infusion of tobacco inert, and consequently should be instantly administered.

*Inorganic emetics*.—The first of these necessary to be noticed, is the *tartrate of antimony and potassa*, a salt which has been employed as an emetic since 1631.† As an emetic, it operates through the medium of the nerves, and probably never until it reaches the circulation. It proves emetic, or purgative, or sudorific, according to the frequency of the dose: thus a grain, dissolved in a moderate quantity of water, given every ten or fifteen minutes, produces full vomiting; the same quantity repeated every three hours may vomit once, but it afterwards purges; and if administered once in six hours only, it causes copious diaphoresis. It is the best of the emetic substances for producing full vomiting at the commencement of continued fevers, and in all cases where it is of advantage to keep up a state of nausea. In mania it is preferable to all other emetics; but it requires to be prescribed in much larger doses than in most other diseases, a scruple often producing little effect whilst the state of congestion of the brain remains; but if the lancet have been previously resorted to, a grain or two grains will produce full vomiting. In melancholia the direct emetics are to be preferred, as the nausea which follows the use of tartar emetic is in this instance injurious, by augmenting the collapse which always occurs in this disease.

When overdosed, besides operating as a powerful emetic, tartar-emetic produces poisonous effects on the mucous coat of the alimentary canal. The best antidotes are infusions of yellow cinchona bark, galls, catechu, or any of the astringent vegetables, the tannin of which unites with the oxide of antimony, and forms an insoluble inert salt. But it is not easy to determine what is an over-

\* Scillitina was first obtained from the squill by Vogel. When pure, it is colourless, intensely bitter, with some sweetness, friable, and resembles a resin in its appearance and fracture, and is equally soluble in water, alcohol, and vinegar. It is deliquescent, gives viscosity to water; but differs from gum in not affording mucic acid when it is treated with nitric acid.

† It was discovered prior to the above date, but was first made known by Adrian Mynsicht, in his treatise entitled, *Thesaurus Medico-Chemicus*.

dose of this salt in disease. The custom of prescribing it in large doses has lately been revived by Rasori and other Italians, and their example has been much followed by all the continental physicians. Laennec states that he gave it to the extent of forty-eight grains, in divided doses, in twenty-four hours, without any deleterious effect, and even without exciting vomiting, except on the first day. Dr. Christie, in a treatise on the nature and treatment of cholera, asserts that he has given  $\text{Bi}$  at once, with the effect only of producing some vomiting and a few watery stools. The writer of this article, who has frequently prescribed it in doses of grs. iii, repeated every third hour, has observed that it seldom causes vomiting after the second or third dose. Rasori explains the power of sustaining such large doses, on the principle that a peculiar diathesis accompanies diseases of excitement, in which only such doses can be borne; and that it ceases as recovery takes place. Laennec, however, says that this power of endurance does not cease at the close of the fever, although it is diminished; a circumstance which, if the observation be correct, may be ascribed to the force of habit.

When tartar emetic proves poisonous, the symptoms resemble those of cholera; violent vomiting, diarrhœa, great pain and tension of the abdomen, and delirium; convulsions supervene, and death sometimes results. These symptoms have sometimes followed the administration of moderate doses. On examination of the body after death, the only marks of previous excitement are slight congestion in the brain, and a thickened state of the villous coat of the stomach and the duodenum, which is covered with a tough mucus.

Tartar emetic is administered in substance, in solution in water, and in solution in wine. The latter preparation is an objectionable one; the free tartaric acid of the wine converting the potassa into a bitartrate, and thus decomposing the triple salt; and the solution should always be made at the time it is to be taken. The solution in wine is chiefly employed in the diseases of children. Some practitioners still adhere to the opinion of Sydenham, who reprobates the use of antimonial remedies for children under eight years of age; but we have never seen any disadvantage follow their administration to children of two or three years of age; nor even, when judiciously employed, to infants at the breast.

A. T. THOMSON.

EMMENAGOGUES, (from  $\epsilon\mu\mu\eta\nu\alpha$ , the menses, and  $\alpha\gamma\omega$ , to induce,) are medicines which promote the menstrual discharge. It has been doubted whether any medicines operate directly upon the uterus; the decided influence of some in promoting its periodical discharge being referred to the diseased organ sharing in the salutary effect of such medicines on the general system. To determine fairly the correctness of this opinion, we must take into consideration the nature of the organ and its function in the unimpregnated state.

The texture of the uterus is fibrous, dense, compact, and abounding in blood-vessels; the veins are destitute of valves: it is also well supplied with nerves, and with lymphatics on its external surface. Internally it is lined with a soft, delicate, spongy membrane, composed chiefly of

capillary vessels. Such is the organ:—what is its function in the unimpregnated state? How far is it adapted to perform the functions of a secreting organ? Is the periodical evacuation derived from it a true secretion, or a mere discharge from vessels oppressed by a local plethora?

In reply to the first query, it is scarcely necessary to say that its function is menstruation; a discharge periodically recurring once a month. The second and third queries involve a matter of controversy; but the prevailing opinion is in favour of the capacity of the uterus to secrete; and, consequently, that the discharge which it exudes is a real secretion. There is nothing in the anatomical structure of the uterus that unfits it for the function of secretion; and were any arguments necessary to refute the notion that menstruation depends on a general plethoric orgasm, it would be only necessary to bring forward the curious facts bearing on this point presented by the Hungarian twin sisters. These two females were united at the lower part of the back, and lived to the age of twenty-two. The same blood flowed in the vessels of each,—for the abdominal vessels were found, after death, united at the loins; yet the uterine function was distinct in both; it differed in its period, and also in the quantity of the discharge. Indeed, in reflecting on the nature of the organ itself, on its resemblance to other glandular organs in the manner in which it is supplied with blood, and on the adaptation of its internal surface to exhalation, we can have little hesitation in admitting that the manner in which the periodical discharge is supplied closely resembles that of a secreted fluid. The uterine arteries are not only exceedingly convoluted, but they are larger and have thinner coats than the veins, in the unimpregnated state: the blood is, therefore, brought into the organ readily and in considerable quantity, whilst it is slowly returned from it,—a state of vessels highly favourable to the secreting function. It is true that, previously to menstruation taking place, there are symptoms indicative of general plethora as well as of local congestion; yet this fact only proves that the discharge is connected with such a state of the system; not that it is caused by this state, nor that the relief which follows is attributable to blood being discharged by the uterine vessels. The admission, also, that there is an increased determination of blood to the organ at the period of menstruation, does not militate against the opinion that the discharge is a secretion; since it is well known that every glandular organ, when excited by its appropriate stimulus, becomes a centre, as it were, to which the blood is directed. Again, if this discharge were merely the effect of a local plethora, it would be blood, which is not the fact; for it does not coagulate like blood, nor does it contain fibrine. If it be thus evident from reasoning, that menstruation is not the mechanical result of a local congestion, let us examine how far observation supports the fact that it is a secretion.

The uterus, as we have already stated, resembles a gland in its vascular supply; and this resemblance extends to its diseases; an inflammatory state existing in it being often followed by scirrhus and cancer. Like other secreting organs, also, its function is often imperfectly performed,

and the secretion, therefore, is liable to vitiation and derangement. In the first efforts of the organ the secretion is usually thin, colourless, defective in quantity, and its recurrence irregular and protracted: when it is suppressed, it cannot be restored by inducing plethora; nor can the flow, when it has commenced, be checked by venesection or any other means of depletion. In making this remark we must not be misunderstood: it is not our intention to assert that inordinate evacuations in other parts of the system do not influence the uterine discharge; on the contrary, we are perfectly aware that preternatural evacuations induced in the other organic systems will suspend the course of the catamenia, on the same principle that increased action of the intestinal system suspends the action of the cutaneous exhalents, and *vice versa*, sweating checks diarrhœa. Any argument founded on the supposition that the structure of the uterus is not sufficiently glandular for a secreting organ must fall to the ground, when we reflect that the gastric juice is secreted by the stomach, an organ still less glandular than the uterus. We shall only add, that the correctness of the opinion that the catamenia are a secretion, does not depend altogether on circumstances connected with the organ itself; experience having ascertained that this discharge is intimately connected with the state of the ovaries; for when these organs are much diseased, or removed, or altogether absent, no menstruation occurs. It is not necessary to the establishment of the truth of our opinion that we should be able to explain the cause of the periodical return of the catamenia.

If menstruation depend, as we believe it does, on the secretory function of the uterus, it is obvious that in the unimpregnated state it ought always to happen at its regular period when the organ is in a natural or healthy state; and that in order to promote its return, when it is interrupted or suspended, such medicines must be employed as will tend to restore the organ to that precise state or condition on which the exercise of this function depends; and it is to these that the appellation *Emmenagogue* can only be properly applied. They may be such as will act either immediately on the uterus itself, or such as will merely influence that organ as a part of the general system; *emmenagogues*, therefore, may be arranged under two heads—*direct* and *indirect*. We shall be able to understand the manner in which both operate, and the propriety of employing the one or the other, only by having a clear idea of the nature of the morbid condition of the organ, and whether the obstruction or interruption of the periodical discharge depend on a diseased state of the uterus itself, or is the effect of the presence of other diseases in the system.

In some instances the suppression of menstruation is a primary affection, "often," as Dr. Denman has justly remarked, "although not universally, succeeded by a certain train of untoward symptoms;" but more frequently it is the result of other diseases; and, therefore, the nature of these, as well as the state of the patient with respect to vigour and constitution of body, must determine the kind of remedial agents to be selected as *emmenagogues*. Thus when the delay of the

regular appearance of the discharge, after it has once appeared, occurs in females with a pale or leucophlegmatic countenance, indicating an atony of the vital powers, stimulant and tonic medicines are required, to give to the vascular system that degree of power which is necessary to maintain the healthy action of the capillaries: on the contrary, when the complexion is florid, when there is much tension of the system, or when the suppression is connected with great irritation of the uterine system, it is easy to understand that menstruation is more likely to be aided by whatever can diminish excitement and soothe and calm irritation than by stimulants. Thence the fact, that very different, nay very opposite remedies are required to remove amenorrhœa, in different instances.

Stimulants, whether corporeal or mental, undoubtedly tend to an early development of the uterine organs, and consequently to the appearance of menstruation sooner than is usual: thus in tropical climates, and in those females who indulge in luxurious and pampered habits, the age of puberty is earlier than in those who inhabit the temperate and frigid zones, and whose habits and passions are better regulated. The continued influence of stimulants is said, also, to prolong menstruation beyond the period of life at which it usually ceases; but this is at least problematical. All *emmenagogues* are more or less stimulants; and in cases in which a stimulant influence is contra-indicated, they cannot be employed until the excitement be reduced, and can then be only employed under certain restrictions.

When the uterine obstruction or irregularity is accompanied with a *pale* complexion and a languid state of the system, a variety of medicines are prescribed, either with a view of directly influencing the uterus by some specific action, or of invigorating the habit, and thence eventually promoting its secretory function. By the indiscreet use of the former, much injury may be done to the organ itself: on the latter, however judiciously prescribed, we cannot always depend; they may improve greatly the general health, and yet the catamenia may not reappear. It ought also to be well understood that idiosyncrasy, natural conformation, diseased states of the uterus itself, or of the ovaries, often are obstacles effectually opposed to the salutary influence of *emmenagogues*. As we have already mentioned, it has been doubted whether there is any medicinal agent which, when taken into the stomach, exerts a direct stimulant influence on the uterus: but if we admit that some substances find their way to particular organs,—for instance, nitre to the kidneys,—there is no reason why such should not be the case with regard to the uterus; experience, however, has not yet demonstrated that this is the case. But a stimulant effect may be propagated from neighbouring parts to the uterine vessels: thence some cathartics, which operate chiefly upon the rectum, influence the uterus.

When the obstruction is accompanied with a florid complexion, and "the colour of the cheeks is the flush, of disease, not the glow of health," (*Denman*;) before taking into consideration the uterine function, bleeding and other antiphlogistic means of treatment must be resorted to and until

the general excitement be subdued, the employment of emmenagogues would be injurious. It is also questionable, whether, even after this has been accomplished, any of the substances supposed to act directly on the uterus should be employed; but if they may be administered, they will be most likely to prove beneficial when given immediately after the reduction of the febrile excitement.

The employment of emmenagogues is not confined to cases of simple obstruction or suppression. In some females the pain with which menstruation is accomplished embitters much of life. Some of the substances employed as emmenagogues are supposed directly to lessen uterine irritation; and thence they are closely allied with sedatives and antispasmodics.

**I. Direct Emmenagogues.**—These may be divided into *immediate* and *mediate*.

1. The only immediate emmenagogue is *electricity*. It is well known that when this powerful agent is passed through any part of the body, a painful sensation is felt at the point of communication. Thus, if the knob of a discharging rod, connected with a chain communicating with the outside of a charged Leyden jar, be applied to one side of the pelvis, and the knob of the jar itself be applied to the side, a feeling will be instantly produced, as if a small sword was thrust through the part, and a stimulant impulse is given to the uterus, by the direct passage of the electrical fluid through it. The stimulant influence of a shock thus communicated, is obvious by the sensation which it excites; but it equally takes place, though in less degree, when no sensation is produced, as when a continued current of the fluid is passed through the organ, by making it a part of a circuit communicating with the prime conductor of an electrical machine. The direct application of electricity is admissible only when a torpor of the uterus exists, indicated by a suppression of the catamenia with a pale complexion and a languid state of the circulation. But even in this state of the habit and the organ, it must be remembered that, whilst applied in moderation, this agent rouses the activity of torpid parts, in large quantity it injures materially, if it do not destroy altogether the excitability of this organ. In employing electricity, therefore, as an emmenagogue, it should be first used under the form of accumulated electricity, or the bath as it is termed, then the aura, and, lastly, shocks should be given. At first, the shock should be moderate; as, in nervous habits, syncope has followed the unguarded communication of powerful shocks; but with ordinary caution in its application, electricity has been found a powerful agent in amenorrhœa, depending either on general debility of the system or atony of the uterus itself. (See *ELECTRICITY*.)

The influence of ergot of rye, *secale cornutum*, on the impregnated uterus, at the period of parturition, has led to the belief that it may be employed as a direct emmenagogue. Admitting that ergot acts directly upon the uterus, it cannot be denied that its influence in parturition is opposed to that which is requisite for exciting the uterine discharge. If menstruation be a secretory action, a certain supply of blood is requisite for its performance; but ergot acting on the motor nerves, and causing muscular contraction, would necessarily lessen this supply,

and produce a state of parts more calculated to impede than to forward the menstrual discharge. Experience has also demonstrated that ergot has indeed very slender pretensions to the character of an emmenagogue.

2. The mediate direct emmenagogues comprehend both organic and inorganic substances. Among the former, madder, the root of the rubia *tinctorum*, has been long employed and relied upon, without any accurate idea of the manner in which it operates; although, from its tinging the urine and the bones of a red colour, it has been supposed that, as it passes into the circulation, it finds its way to the uterus, and directly influences that organ. The late Dr. Barton, an American physician of eminence, placed great reliance on its deobstruent powers; and it was also much esteemed by the late Dr. Home, of Edinburgh, who, in his clinical experiments and histories, has recorded his decided opinion of its efficacy as an emmenagogue. He gave it in doses of from  $\mathfrak{ss}$  to  $\mathfrak{z}\mathfrak{i}$ , twice or three times a day. But notwithstanding these authorities, madder is an equivocal emmenagogue, and is now rarely or never employed.

*Savine*, the leaves and herbaceous part of the juniperus *sabina*, which owes its stimulant properties to a volatile oil having some affinity to that of turpentine, is an energetic emmenagogue; and from its proneness to produce uterine hemorrhage, and cause abortion, there is some reason for the opinion that the volatile oil is taken into the circulation and acts directly upon the uterus, on which it exerts a stimulant influence. More than a century ago, its tendency to produce abortion led to its employment as an emmenagogue; but from an opinion expressed by Dr. Cullen, it fell into disrepute. In whatever manner it acts, savine, or its oil, is well adapted for cases of amenorrhœa connected with a feeble state of the constitution, and a languid circulation. The dose of the powder is from gr. v. to gr. x.; that of the oil, which can be readily formed into an oleo-saccharum, from m.ii. to m.vi. The extract, ordered by the Dublin Pharmacopœia, is a useless preparation; the volatile oil being dissipated by the heat necessary to be used in forming the extract.

*Seneka root*, the root of the polygala *senega*, is esteemed a useful and active emmenagogue by the American physicians. The active principle, which is supposed to be a peculiar salt, first noticed by Peschier, and named by him polygaline or polygalina,\* resides in the bark of the root. Dr. Hartshorne, of Philadelphia, who first employed it as an emmenagogue, found that it was most useful in recent cases of amenorrhœa. He began its use two weeks previous to the expected appearance of the catamenia, giving it in the form of a saturated decoction, to the extent of a pint in twenty-four hours, pushing the dose as far as the stomach would permit, until the discharge appeared. Dr. Chapman, of Pennsylvania, adds his testimony to that of Dr. Hartshorne in favour of senega root, and believes that it exerts a specific action on the uterus; but it ought to be mentioned that the patient is directed to be prepared by an alterative course of calomel, carried to gentle ptyalism; on

\* Peschier procured gr. 100 of this salt from 6 ounces of the root. He asserts that it is united with a peculiar acid, which he has called *polygalinic*.

which account it is difficult to say how much is due to the mercurial, how much to the senega. If, however, the observations of the American physicians be correct, *polygala senega* merits the attention of British practitioners as an emmenagogue.

No medicines perhaps merit more the appellation of direct mediate emmenagogues than the preparations of *mercury*. They effect almost a specific change upon the whole glandular system; and, consequently, if the glandular nature of the uterine function be admitted, it is easy to conceive that they are likely to affect the capillaries in the uterus, when these are in an unnatural or morbid condition. The preparation best suited for emmenagogue purposes is calomel; it is mild in its operation, and at the same time certain in its influence on the general system. In the combination in which it exists in Plummer's pill in particular, it has been found highly beneficial, the precipitated sulphuret of antimony greatly aiding its power. In this combination, it may be given in doses of from five to twelve grains every night and morning, until the gums be sensibly affected.

From what has been said, it is obvious that electricity is the only direct emmenagogue, and that the idea of the others acting upon the uterus itself is rather inferred than certain. It is nevertheless true, that, in whatever manner they act, they stimulate the uterus; and, therefore, some caution is requisite to be observed in their administration. Thus we must be certain that the suppression is not connected with pregnancy; and even when this is not the case, there is some difficulty in deciding upon the propriety of administering direct and stimulant emmenagogues; the uterus may be in such a state of active disease, as to render their influence upon it extremely hazardous.

**II. Indirect Emmenagogues.** The operation of these is effected in three ways:

1. By the substance operating on the kidneys or the intestinal canal, and stimulating the uterus by proximity.

2. By the substance acting on the stomach and improving the general health, so that the uterus shares the general salutary influence.

3. The uterus may be specifically acted upon through the medium of the nervous system.

The substances that operate in the first manner are, some diuretics, and those cathartics which especially stimulate the rectum. The diuretics are such as pass to the kidneys undecomposed, and powerfully stimulate these organs: thus nitre administered in doses of from  $\mathfrak{z}\text{i}$  to  $\mathfrak{z}\text{ij}$ , in any bland fluid, possesses decided emmenagogue powers. Foxglove operates in the same manner. Among the emmenagogue cathartics, aloes holds the first rank. Its influence can only be referred to its action on the rectum, and its extension to the uterus, producing a state of the organ closely allied to that which is the result of the application of a direct stimulus to it. The powerful sympathetic influence of aloetics is well illustrated by the effect which sometimes follows their administration after the total cessation of the catamenia. For a certain period after this event takes place, the uterus retains the disposition to take on that state of vascular action which determines the peri-

odical discharge; but it is incapable by its natural efforts to effect the discharge. In this state of uterine susceptibility, the excitement of the rectum by an aloetic purgative almost invariably induces the return of the menses in a slight degree, provided the cathartic be given at the period when the discharge had previously been accustomed to appear. Now if a purgative produce so powerful a sympathetic action when this uterine function has ceased to be any longer essential, we can readily imagine that a more powerful effect is likely to be the result of a similar extension of action from the rectum to the uterus at a period of life when the susceptibility to uterine impressions exists in a high degree. Experience has sufficiently demonstrated that such an extension of action really occurs. In prescribing aloes, however, as an emmenagogue, the cause of the suppression must be kept in view; for this medicine cannot be safely administered in an irritable state of the uterus. To secure its influence on the uterus, it is supposed necessary to administer the medicine in a solid form; but we are of opinion that this supposition is founded on a mistaken idea of its mode of acting; we have seen it most successful when it has been prescribed in conjunction with alkalies, which greatly aid its solubility. The administration of a pill containing one grain of calomel, the same quantity of powder of digitalis, and three of extract of conium, at bed-time, followed in the morning, by half an ounce of wine of aloes and myrrh, in conjunction with the mineral alkalies and ammonia, (See London Dispensatory, sixth edit. p. 941,) for two or three days previous to the expected return of the menstrual discharge, have, in our hands, proved generally successful. We are usually advised to avoid recommending the use of aloetics to persons subject to hemorrhoids; but although they operate chiefly on the large intestines, the idea that they produce hemorrhoids, or even rouse them to activity in those affected by them, unless the dose be very large, is doubtful.

*Black hellebore*, *radix hellebori nigri*, is another useful emmenagogue purgative of this class, adapted to plethoric habits: it probably acts by reducing that state of the system which is as adverse to the secretory action of every glandular organ as to that of the uterus. Mead pronounced a high eulogy on the emmenagogue properties of black hellebore; and it continued to be much employed until doubts of its efficacy were raised by Cullen and Heberden,\* after which it fell into disrepute; but it is still much prescribed on the continent of Europe and in the United States of America. Dr. Chapman thus expresses himself regarding it: "It is especially useful when it purges, in painful menstruation, attended with torpor and constipation of the bowels, and perhaps with some degree of insensibility in the uterus itself." (*Materia Medica*.) From the violence of its action as a purgative, black hellebore requires to be administered with caution. If it be employed, the tincture is the best form of preparation; it may be added to any purgative, and thus aid in stimulat-

\* *Radix hellebori nigri facultatem movendi menstrua sibi vindicavit, quam tamen nullo satis firmo argumento usus mihi confirmavit.*—*Commentarii de Morb. Hist. et Cur.* p. 261.

ing the uterus with less risk than is likely to attend the use of the root in substance or its infusion. The extract of the Edinburgh Pharmacopœia, in doses of from gr. iv. to gr. x., combined with extract of conium, has been found useful in the amenorrhœa of chlorotic girls. The same remarks apply to camboë. *Serpentaria*, valerian, and wormwood, have been employed, in various combinations, to produce emmenagogue effects, and seem to operate chiefly as stimulant antispasmodics. As such, the preparation of valerian, particularly the ammoniated tincture, is indicated in hysterical habits, when the circulation is in a languid state, and the menstrual discharge ushered in with an hysterical paroxysm: it seems to act chiefly by soothing the nervous turbulence; and may be given in doses of from fʒi to fʒii, in combination with decoction of aloes.

The inorganic substances in this division of emmenagogues are, principally, salts of iron, both natural and artificial. The former, which, as they exist in chalybeate waters, are carbonates or sulphates, are most beneficial when drunk at the springs; they raise the pulse in strength, and distribute the blood more equally; and, although the quantity of iron contained in the dose of the water, generally half a pint, be extremely small, yet it operates as a decided stimulant tonic. In plethoric individuals, it is often requisite to bleed and purge before the use of the chalybeate is commenced; and if nausea, pain of the præcordia, vomiting, vertigo, or a feeling of general fullness be, nevertheless, experienced after the waters have been taken, they should immediately be discontinued. All the varieties of chalybeate water prove beneficial in amenorrhœa connected with a pale leucophlegmatic habit; their operation is on the secretory system, which they influence in a slow but uniformly progressive manner, imparting tone, nervous energy, and general vigour. When the habit of the patient is sluggish, the *pilula aloes cum myrrha* may be administered with each dose of the water. The whole quantity of the chalybeate necessary to be taken in one day should be drunk in divided doses, betwixt each of which brisk walking exercise should be used. The artificial preparations require to be given in much larger doses than those contained in the chalybeate waters, a circumstance which has not been satisfactorily explained. The most common of the artificial preparations employed in amenorrhœa is the officinal *black oxide* of iron, the scales from the anvil purified. It is a compound of the protoxide and peroxide; the former of which combines readily with the acid of the stomach. The dose is from gr. v. to ℥i; it may be combined with an aromatic, and administered two or three times a day. Neither the *liquor ferri alkalini*, nor the *ferrum ammoniatum*, are active preparations:

perhaps the most energetic of all the artificial chalybeates is the tincture of muriated iron; and it possesses the advantage of being compatible with many bitter tonic infusions and decoctions; as, for example, those of gentian, quassia, orange-peel, and such like. If the sulphate of iron be preferred, it should always be in the form of the proto-sulphate; but as this salt is rapidly converted into the persulphate when it is kept in the usual manner, it should be preserved in alcohol.\* In the formation, also, of the *mistura ferri composita*, it would be preferable to add the sulphate of iron in solution to the mixture of myrrh and subcarbonate of potassa at the moment of taking the medicine, than to prepare it as ordered in the London and Dublin Pharmacopœia. When previously mixed, the carbonate of iron, which is at first formed by the exchange of acids between the salt of iron and the alkaline carbonate, is again rapidly decomposed, and transmuted into an inert peroxide of iron; whereas, when managed as we propose, the protocarbonate is formed in the stomach, and immediately exerts its influence upon it, operating as a powerful and effectual tonic emmenagogue. The dose of the protosulphate proper to mix with fʒiiss and of the myrrh and alkaline solution is four grains. Its influence is perceived by the rapid change which it induces on the alvine and renal evacuations; the black colour of the former, and the blue streak when the latter is tested with ferro-cyanate of potassa, demonstrating that the chalybeate has entered the circulation.

The mediate indirect emmenagogues, which influence the uterine function by their action on the nervous system, are all organic substances, both animal and vegetable. Their influence is chiefly useful when amenorrhœa accompanies highly irritable habits, and the suppression is connected with spasm and hysteria. We are of opinion that much confidence cannot be given to *castor* or to *musk*; galbanum and assafœtida are more useful; but they are to be regarded merely as aids to more powerful indirect emmenagogues.

On reviewing what has been said on this subject, it is evident that, with the exception of electricity, there is no method of directly stimulating the uterus on which much confidence can be placed; for little benefit has hitherto been derived from stimulating injections; and under these circumstances it may be reasonably questioned whether any medicinal agent can be correctly entitled to the appellation *emmenagogue*.

A. T. THOMSON.

\* Green vitriol consists of 36 parts of protoxide of iron, + 40 of sulphuric acid, + 63 of water of crystallization, = 139; when exposed to the air, oxygen is absorbed, and an insoluble subsulphate produced which consists of 40 parts of acid, + 160 peroxide of iron, = 200.

# BLANCHARD & LEA'S MEDICAL AND SURGICAL PUBLICATIONS.

## TO THE MEDICAL PROFESSION.

The prices on the present catalogue are those at which our books can generally be furnished by booksellers throughout the United States, who can readily procure any which they may not have on hand. To physicians who have not convenient access to bookstores, we will, as long as the existing rates of postage remain unchanged, forward them at these prices, *free* by mail, to any post-office in the United States under 1,500 miles. As we open accounts only with booksellers, the amount must in every case, without exception, accompany the order, and we assume no risks of the mail, either on the money or on the books; and as we deal only in our own publications, we can supply no others. Gentlemen desirous of purchasing will, therefore, find it more advantageous to deal with the nearest booksellers whenever practicable.

BLANCHARD & LEA.

PHILADELPHIA, July, 1862.

\* \* We have now ready a new edition of our ILLUSTRATED CATALOGUE of Medical and Scientific Publications, forming an octavo pamphlet of 80 large pages, containing specimens of illustrations, notices of the medical press, &c. &c. It has been prepared without regard to expense, and will be found one of the handsomest specimens of typographical execution as yet presented in this country. Copies will be sent to any address, by mail, free of postage, on receipt of nine cents in stamps.

Catalogues of our numerous publications in miscellaneous and educational literature forwarded on application.

 The attention of physicians is especially solicited to the following important new works and new editions, just issued or nearly ready:—

Ashton on the Rectum, . . . . .	See page	3
Bumstead on Venereal, . . . . .	"	5
Barclay on Medical Diagnosis, . . . . .	"	5
Barwell on the Joints, . . . . .	"	6

## TWO MEDICAL PERIODICALS, FREE OF POSTAGE,

Containing over Fifteen Hundred large octavo pages,

## FOR FIVE DOLLARS PER ANNUM.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, subject to postage, when not paid for in advance, - - - - - \$5 00  
 THE MEDICAL NEWS AND LIBRARY, invariably in advance, - - - - - 1 00  
 OR, BOTH PERIODICALS mailed, FREE OF POSTAGE (as long as the existing rates are maintained), to any post-office in the United States, for Five Dollars remitted in advance.

## THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY ISAAC HAYS, M. D.,

is published Quarterly, on the first of January, April, July, and October. Each number contains at least two hundred and eighty large octavo pages, handsomely and appropriately illustrated,

wherever necessary. It has now been issued regularly for more than forty years, and it has been under the control of the present editor for more than a quarter of a century. Throughout this long period, it has maintained its position in the highest rank of medical periodicals both at home and abroad, and has received the cordial support of the entire profession in this country. Its list of Collaborators will be found to contain a large number of the most distinguished names of the profession in every section of the United States, rendering the department devoted to

## ORIGINAL COMMUNICATIONS

full of varied and important matter, of great interest to all practitioners.

As the aim of the Journal, however, is to combine the advantages presented by all the different varieties of periodicals, in its

## REVIEW DEPARTMENT

will be found extended and impartial reviews of all important new works, presenting subjects of novelty and interest, together with very numerous

## BIBLIOGRAPHICAL NOTICES,

including nearly all the medical publications of the day, both in this country and Great Britain, with a choice selection of the more important continental works. This is followed by the

## QUARTERLY SUMMARY,

being a very full and complete abstract, methodically arranged, of the

## IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES.

This department of the Journal, so important to the practising physician, is the object of especial care on the part of the editor. It is classified and arranged under different heads, thus facilitating the researches of the reader in pursuit of particular subjects, and will be found to present a very full and accurate digest of all observations, discoveries, and inventions recorded in every branch of medical science. The very extensive arrangements of the publishers are such as to afford to the editor complete materials for this purpose, as he not only regularly receives

## ALL THE AMERICAN MEDICAL AND SCIENTIFIC PERIODICALS,

but also twenty or thirty of the more important Journals issued in Great Britain and on the Continent, thus enabling him to present in a convenient compass a thorough and complete abstract of everything interesting or important to the physician occurring in any part of the civilized world.

To their old subscribers, many of whom have been on their list for twenty or thirty years, the publishers feel that no promises for the future are necessary; but those who may desire for the first time to subscribe, can rest assured that no exertion will be spared to maintain the Journal in the high position which it has occupied for so long a period.

By reference to the terms it will be seen that, in addition to this large amount of valuable and practical information on every branch of medical science, the subscriber, by paying in advance, becomes entitled, without further charge, to

## THE MEDICAL NEWS AND LIBRARY,

a monthly periodical of thirty-two large octavo pages. Its "NEWS DEPARTMENT" presents the current information of the day, while the "LIBRARY DEPARTMENT" is devoted to presenting standard works on various branches of medicine. Within a few years, subscribers have thus received, without expense, many works of the highest character and practical value, such as "Watson's Practice," "Todd and Bowman's Physiology," "Malgaigne's Surgery," "West on Children," "West on Females, Part I.," "Haber-hon on the Alimentary Canal," &c.

While the work at present appearing in its columns is

## CLINICAL LECTURES ON THE DISEASES OF WOMEN.

By PROFESSOR J. Y. SIMPSON, of Edinburgh.

## WITH NUMEROUS HANDSOME ILLUSTRATIONS.

These Lectures, published in England under the supervision of the Author, carry with them all the weight of his wide experience and distinguished reputation. Their eminently practical nature, and the importance of the subject treated, cannot fail to render them in the highest degree satisfactory to subscribers, who can thus secure them without cost. These Lectures are continued in the "News" for 1862.

It will thus be seen that for the small sum of FIVE DOLLARS, paid in advance, the subscriber will obtain a Quarterly and a Monthly periodical,

## EMBRACING NEARLY SIXTEEN HUNDRED LARGE OCTAVO PAGES.

Those subscribers who do not pay in advance will bear in mind that their subscription of Five Dollars will entitle them to the Journal only, without the News, and that they will be at the expense of their own postage on the receipt of each number. The advantage of a remittance when ordering the Journal will thus be apparent.

Remittances of subscriptions can be mailed at our risk, when a certificate is taken from the Postmaster that the money is duly inclosed and forwarded.

Address **BLANCHARD & LEA, PHILADELPHIA.**

**ASHTON (T. J.),**

Surgeon to the Blenheim Dispensary, &amp;c.

**ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS;** with remarks on Habitual Constipation. From the third and enlarged London edition. With handsome illustrations. In one very beautifully printed octavo volume, of about 300 pages. (*Just Issued.*) \$2 00.

The most complete one we possess on the subject. *Medico-Chirurgical Review.*

We are satisfied, after a careful examination of the volume, and a comparison of its contents with those of its leading predecessors and contemporaries, that the best way for the reader to avail himself of

the excellent advice given in the concluding paragraph above, would be to provide himself with a copy of the book from which it has been taken, and diligently to con its instructive pages. They may secure to him many a triumph and fervent blessing.—*Am. Journal Med. Sciences.*

**ALLEN (J. M.), M. D.,**

Professor of Anatomy in the Pennsylvania Medical College, &amp;c.

**THE PRACTICAL ANATOMIST;** or, **The Student's Guide in the Dissecting-ROOM.** With 266 illustrations. In one handsome royal 12mo. volume, of over 600 pages, leather. \$2 25.

We believe it to be one of the most useful works upon the subject ever written. It is handsomely illustrated, well printed, and will be found of convenient size for use in the dissecting-room.—*Med. Examiner.*

However valuable may be the "Dissector's Guides" which we, of late, have had occasion to

notice, we feel confident that the work of Dr. Allen is superior to any of them. We believe with the author, that none is so fully illustrated as this, and the arrangement of the work is such as to facilitate the labors of the student. We most cordially recommend it to their attention.—*Western Lancet.*

**ANATOMICAL ATLAS.**

By Professors H. H. SMITH and W. E. HORNER, of the University of Pennsylvania. 1 vol. 8vo., extra cloth, with nearly 650 illustrations. See SMITH, p. 331.

**ABEL (F. A.), F. C. S. AND C. L. BLOXAM.**

**HANDBOOK OF CHEMISTRY,** Theoretical, Practical, and Technical; with a Recommendatory Preface by Dr. Hofmann. In one large octavo volume, extra cloth, of 662 pages, with illustrations. \$3 25.

**ASHWELL (SAMUEL), M. D.,**

Obstetric Physician and Lecturer to Guy's Hospital, London.

**A PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN.**

Illustrated by Cases derived from Hospital and Private Practice. Third American, from the Third and revised London edition. In one octavo volume, extra cloth, of 528 pages. \$3 00.

The most useful practical work on the subject in the English language.—*Boston Med. and Surg. Journal.*

The most able, and certainly the most standard and practical, work on female diseases that we have yet seen.—*Medico-Chirurgical Review.*

**ARNOTT (NEILL), M. D.**

**ELEMENTS OF PHYSICS;** or **Natural Philosophy, General and Medical.**

Written for universal use, in plain or non-technical language. A new edition, by ISAAC HAYS, M. D. Complete in one octavo volume, leather, of 484 pages, with about two hundred illustrations. \$2 50.

**BIRD (GOLDING), A. M., M. D., &c.**

**URINARY DEPOSITS: THEIR DIAGNOSIS, PATHOLOGY, AND THERAPEUTICAL INDICATIONS.** Edited by EDMUND LLOYD BIRKETT, M. D. A new American, from the fifth and enlarged London edition. With eighty illustrations on wood. In one handsome octavo volume, of about 400 pages, extra cloth. \$2 00. (*Just Issued.*)

The death of Dr. Bird has rendered it necessary to entrust the revision of the present edition to other hands, and in his performance of the duty thus devolving on him, Dr. Birkett has sedulously endeavored to carry out the author's plan by introducing such new matter and modifications of the text as the progress of science has called for. Notwithstanding the utmost care to keep the work within a reasonable compass, these additions have resulted in a considerable enlargement. It is, therefore, hoped that it will be found fully up to the present condition of the subject, and that the reputation of the volume as a clear, complete, and compendious manual, will be fully maintained.

**BENNETT (J. HUGHES), M. D., F. R. S. E.,**

Professor of Clinical Medicine in the University of Edinburgh, &amp;c.

**THE PATHOLOGY AND TREATMENT OF PULMONARY TUBERCULOSIS,** and on the Local Medication of Pharyngeal and Laryngeal Diseases frequently mistaken for or associated with, Phthisis. One vol. 8vo., extra cloth, with wood-cuts. pp. 130. \$1 25.

**BARLOW (GEORGE H.), M. D.**

Physician to Guy's Hospital, London, &amp;c.

**A MANUAL OF THE PRACTICE OF MEDICINE.** With Additions by D. F. CONDIE, M. D., author of "A Practical Treatise on Diseases of Children," &c. In one handsome octavo volume, leather, of over 600 pages. \$2 75.

We recommend Dr. Barlow's Manual in the warmest manner as a most valuable vade-mecum. We have had frequent occasion to consult it, and have

found it clear, concise, practical, and sound.—*Boston Med. and Surg. Journal.*

**BUDD (GEORGE), M. D., F. R. S.,**  
Professor of Medicine in King's College, London.

**ON DISEASES OF THE LIVER.** Third American, from the third and enlarged London edition. In one very handsome octavo volume, extra cloth, with four beautifully colored plates, and numerous wood-cuts. pp. 500. \$3 00.

Has fairly established for itself a place among the classical medical literature of England.—*British and Foreign Medico-Chir. Review.*

Dr. Budd's Treatise on Diseases of the Liver is now a standard work in Medical literature, and during the intervals which have elapsed between the successive editions, the author has incorporated into the text the most striking novelties which have characterized the recent progress of hepatic physiology and pathology; so that although the size of the book

is not perceptibly changed, the history of liver diseases is made more complete, and is kept upon a level with the progress of modern science. It is the best work on Diseases of the Liver in any language.—*London Med. Times and Gazette.*

This work, now the standard book of reference on the diseases of which it treats, has been carefully revised, and many new illustrations of the views of the learned author added in the present edition.—*Dublin Quarterly Journal.*

BY THE SAME AUTHOR.

**ON THE ORGANIC DISEASES AND FUNCTIONAL DISORDERS OF THE STOMACH.** In one neat octavo volume, extra cloth. \$1 50.

**BUCKNILL (J. C.), M. D.,** AND **DANIEL H. TUKE, M. D.,**  
Medical Superintendent of the Devon Lunatic Asylum. Visiting Medical Officer to the York Retreat.

**A MANUAL OF PSYCHOLOGICAL MEDICINE;** containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of INSANITY. With a Plate. In one handsome octavo volume, of 536 pages. \$3 00.

The increase of mental disease in its various forms, and the difficult questions to which it is constantly giving rise, render the subject one of daily enhanced interest, requiring on the part of the physician a constantly greater familiarity with this, the most perplexing branch of his profession. At the same time there has been for some years no work accessible in this country, presenting the results of recent investigations in the Diagnosis and Prognosis of Insanity, and the greatly improved methods of treatment which have done so much in alleviating the condition or restoring the health of the insane. To fill this vacancy the publishers present this volume, assured that the distinguished reputation and experience of the authors will entitle it at once to the confidence of both student and practitioner. Its scope may be gathered from the declaration of the authors that "their aim has been to supply a text book which may serve as a guide in the acquisition of such knowledge, sufficiently elementary to be adapted to the wants of the student, and sufficiently modern in its views and explicit in its teaching to suffice for the demands of the practitioner."

**BENNETT (HENRY), M. D.**

**A PRACTICAL TREATISE ON INFLAMMATION OF THE UTERUS, ITS CERVIX AND APPENDAGES,** and on its connection with Uterine Disease. To which is added, a Review of the present state of Uterine Pathology. Fifth American, from the third English edition. In one octavo volume, of about 500 pages, extra cloth. \$2 00.

**BROWN (ISAAC BAKER),**

Surgeon-Accoucheur to St. Mary's Hospital, &c.

**ON SOME DISEASES OF WOMEN ADMITTING OF SURGICAL TREATMENT.** With handsome illustrations. One vol. 8vo., extra cloth, pp. 276. \$1 60.

Mr. Brown has earned for himself a high reputation in the operative treatment of sundry diseases and injuries to which females are peculiarly subject. We can truly say of his work that it is an important addition to obstetrical literature. The operative suggestions and contrivances which Mr. Brown describes, exhibit much practical sagacity and skill,

and merit the careful attention of every surgeon-accoucheur.—*Association Journal.*

We have no hesitation in recommending this book to the careful attention of all surgeons who make female complaints a part of their study and practice.—*Dublin Quarterly Journal.*

**BOWMAN (JOHN E.), M. D.**

**PRACTICAL HANDBOOK OF MEDICAL CHEMISTRY.** Second American, from the third and revised English Edition. In one neat volume, royal 12mo., extra cloth, with numerous illustrations. pp. 288. \$1 25.

BY THE SAME AUTHOR.

**INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS.** Second American, from the second and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., extra cloth. pp. 350. \$1 25.

**BEALE ON THE LAWS OF HEALTH IN RELATION TO MIND AND BODY.** A Series of Letters from an old Practitioner to a Patient. In one volume, royal 12mo., extra cloth. pp. 296. 80 cents.

**BUSHNAN'S PHYSIOLOGY OF ANIMAL AND VEGETABLE LIFE;** a Popular Treatise on the Functions and Phenomena of Organic Life. In one handsome royal 12mo. volume, extra cloth, with over 100 illustrations. pp. 234. 80 cents.

**BUCKLER ON THE ETIOLOGY, PATHOLOGY, AND TREATMENT OF FIBRO-BRONCHITIS AND RHEUMATIC PNEUMONIA.** In one 8vo. volume, extra cloth. pp. 150. \$1 25.

**BLOOD AND URINE (MANUALS ON).** BY JOHN WILLIAM GRIFFITH, G. OWEN REESE, AND ALFRED MARKWICK. One thick volume, royal 12mo., extra cloth, with plates. pp. 460. \$1 25.

**BRODIE'S CLINICAL LECTURES ON SURGERY.** 1 vol. 8vo. cloth. 350 pp. \$1 25.

**BUMSTEAD (FREEMAN J.) M. D.,**

Lecturer on Venereal Diseases at the College of Physicians and Surgeons, New York, &c.

**THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES,** including the results of recent investigations upon the subject. With illustrations on wood. In one very handsome octavo volume, of nearly 700 pages, extra cloth; \$3 75. (*Now Ready.*)

By far the most valuable contribution to this particular branch of practice that has seen the light within the last score of years. His clear and accurate descriptions of the various forms of venereal disease, and especially the methods of treatment he proposes, are worthy of the highest encomium. In these respects it is better adapted for the assistance of the every-day practitioner than any other with which we are acquainted. In variety of methods proposed, in minuteness of direction, guided by careful discrimination of varying forms and complications, we write down the book as unsurpassed. It is a work which should be in the possession of every practitioner.—*Chicago Med. Journal*, Nov. 1861.

The foregoing admirable volume comes to us, embracing the whole subject of syphilology, resolving many a doubt, correcting and confirming many an entertained opinion, and in our estimation the best, completest, fullest monograph on this subject in our language. As far as the author's labors themselves are concerned, we feel it a duty to say that he has not only exhausted his subject, but he has presented to us, without the slightest hyperbole, the best digested treatise on these diseases in our language. He has carried its literature down to the present moment, and has achieved his task in a manner which cannot but redound to his credit.—*British American Journal*, Oct. 1861.

We believe this treatise will come to be regarded as high authority in this branch of medical practice, and we cordially commend it to the favorable notice of our brethren in the profession. For our own part, we candidly confess that we have received many new ideas from its perusal, as well as modified many views which we have long, and, as we now think, erroneously entertained on the subject of syphilis.

To sum up all in a few words, this book is one which no practising physician or medical student can very well afford to do without.—*American Med. Times*, Nov. 2, 1861.

The whole work presents a complete history of venereal diseases, comprising much interesting and valuable material that has been spread through medical journals within the last twenty years—the period of many experiments and investigations on the subject—the whole carefully digested by the aid of the author's extensive personal experience, and offered to the profession in an admirable form. Its completeness is secured by good plates, which are especially full in the anatomy of the genital organs. We have examined it with great satisfaction, and congratulate the medical profession in America on the nationality of a work that may fairly be called original.—*Berkshire Med. Journal*, Dec. 1861.

One thing, however, we are impelled to say, that we have met with no other book on syphilis, in the English language, which gave so full, clear, and impartial views of the important subjects on which it treats. We cannot, however, refrain from expressing our satisfaction with the full and perspicuous manner in which the subject has been presented, and the careful attention to minute details, so useful—not to say indispensable—in a practical treatise. In conclusion, if we may be pardoned the use of a phrase now become stereotyped, but which we here employ in all seriousness and sincerity, we do not hesitate to express the opinion that Dr. Bumstead's Treatise on Venereal Diseases is a "work without which no medical library will hereafter be considered complete."—*Boston Med. and Surg. Journal*, Sept. 5, 1861.

**BARCLAY (A. W.), M. D.,**

Assistant Physician to St. George's Hospital, &c.

**A MANUAL OF MEDICAL DIAGNOSIS; being an Analysis of the Signs and Symptoms of Disease.** Second American from the second and revised London edition. In one neat octavo volume, extra cloth, of 451 pages. \$2 25. (*Now ready.*)

The demand for a second edition of this work shows that the vacancy which it attempts to supply has been recognized by the profession, and that the efforts of the author to meet the want have been successful. The revision which it has enjoyed will render it better adapted than before to afford assistance to the learner in the prosecution of his studies, and to the practitioner who requires a convenient and accessible manual for speedy reference in the exigencies of his daily duties. For this latter purpose its complete and extensive Index renders it especially valuable, offering facilities for immediately turning to any class of symptoms, or any variety of disease.

The task of composing such a work is neither an easy nor a light one; but Dr. Barclay has performed it in a manner which meets our most unqualified approbation. He is no mere theorist; he knows his work thoroughly, and in attempting to perform it, has not exceeded his powers.—*British Med. Journal*.

We venture to predict that the work will be deservedly popular, and soon become, like Watson's Practice, an indispensable necessity to the practitioner.—*N. A. Med. Journal*.

An inestimable work of reference for the young practitioner and student.—*Nashville Med. Journal*.

We hope the volume will have an extensive circulation, not among students of medicine only, but practitioners also. They will never regret a faithful study of its pages.—*Cincinnati Lancet*.

An important acquisition to medical literature. It is a work of high merit, both from the vast importance of the subject upon which it treats, and also from the real ability displayed in its elaboration. In conclusion, let us bespeak for this volume that attention of every student of our art which it so richly deserves—that place in every medical library which it can so well adore.—*Peninsular Medical Journal*.

**BARTLETT (ELISHA), M. D.**

**THE HISTORY, DIAGNOSIS, AND TREATMENT OF THE FEVERS OF THE UNITED STATES.** A new and revised edition. By ALONZO CLARK, M. D., Prof. of Pathology and Practical Medicine in the N. Y. College of Physicians and Surgeons, &c. In one octavo volume, of six hundred pages, extra cloth. Price \$3 00.

It is a work of great practical value and interest, containing much that is new relative to the several diseases of which it treats, and, with the additions of the editor, is fully up to the times. The distinctive features of the different forms of fever are plainly and forcibly portrayed, and the lines of demarcation carefully and accurately drawn, and to the American practitioner is a more valuable and safe guide than any work on fever extant.—*Ohio Med. and Surg. Journal*.

This excellent monograph on febrile disease, has

stood deservedly high since its first publication. It will be seen that it has now reached its fourth edition under the supervision of Prof. A. Clark, a gentleman who, from the nature of his studies and pursuits, is well calculated to appreciate and discuss the many intricate and difficult questions in pathology. His annotations add much to the interest of the work, and have brought it well up to the condition of the science as it exists at the present day in regard to this class of diseases.—*Southern Med. and Surg. Journal*.

BARWELL (RICHARD,) F. R. C. S.,  
Assistant Surgeon Charing Cross Hospital, &c.

**A TREATISE ON DISEASES OF THE JOINTS.** Illustrated with engravings on wood. In one very handsome octavo volume, of about 500 pages, extra cloth; \$3 00. (*Now Ready.*)

"A treatise on Diseases of the Joints equal to, or rather beyond the current knowledge of the day, has long been required—my professional brethren must judge whether the ensuing pages may supply the deficiency. No author is fit to estimate his own work at the moment of its completion, but it may be permitted me to say that the study of joint diseases has very much occupied my attention, even from my studentship, and that for the last six or eight years my devotion to that subject has been almost unremitting. . . . The real weight of my work has been at the bedside, and the greatest labor devoted to interpreting symptoms and remedying their cause."—AUTHOR'S PREFACE.

At the outset we may state that the work is worthy of much praise, and bears evidence of much thoughtful and careful inquiry, and here and there of no slight originality. We have already carried this notice further than we intended to do, but not to the extent the work deserves. We can only add, that the perusal of it has afforded us great pleasure. The author has evidently worked very hard at his subject, and his investigations into the Physiology and Pathology of Joints have been carried on in a manner which entitles him to be listened to with attention and respect. We must not omit to mention the very admirable plates with which the volume is enriched. We seldom meet with such striking and faithful delineations of disease.—*London Med. Times and Gazette*, Feb. 9, 1861.

We cannot take leave, however, of Mr. Barwell, without congratulating him on the interesting amount of information which he has compressed into his book. The work appears to us calculated

to be of much use to the practising surgeon who may be in want of a treatise on diseases of the joints, and at the same time one which contains the latest information on articular affections and the operations for their cure.—*Dublin Med. Press*, Feb. 27, 1861.

This volume will be welcomed, both by the pathologist and the surgeon, as being the record of much honest research and careful investigation into the nature and treatment of a most important class of disorders. We cannot conclude this notice of a valuable and useful book without calling attention to the amount of *bonâ fide* work it contains. In the present day of universal book-making, it is no slight matter for a volume to show laborious investigation, and at the same time original thought, on the part of its author, whom we may congratulate on the successful completion of his arduous task.—*London Lancet*, March 9, 1861.

CARPENTER (WILLIAM B.), M. D., F. R. S., &c.,  
Examiner in Physiology and Comparative Anatomy in the University of London.

**PRINCIPLES OF HUMAN PHYSIOLOGY;** with their chief applications to

Psychology, Pathology, Therapeutics, Hygiene, and Forensic Medicine. A new American, from the last and revised London edition. With nearly three hundred illustrations. Edited, with additions, by FRANCIS GURNEY SMITH, M. D., Professor of the Institutes of Medicine in the Pennsylvania Medical College, &c. In one very large and beautiful octavo volume, of about nine hundred large pages, handsomely printed and strongly bound in leather, with raised bands. \$4 25.

In the preparation of this new edition, the author has spared no labor to render it, as heretofore, a complete and lucid exposition of the most advanced condition of its important subject. The amount of the additions required to effect this object thoroughly, joined to the former large size of the volume, presenting objections arising from the unwieldy bulk of the work, he has omitted all those portions not bearing directly upon HUMAN PHYSIOLOGY, designing to incorporate them in his forthcoming Treatise on GENERAL PHYSIOLOGY. As a full and accurate text-book on the Physiology of Man, the work in its present condition therefore presents even greater claims upon the student and physician than those which have heretofore won for it the very wide and distinguished favor which it has so long enjoyed. The additions of Prof. Smith will be found to supply whatever may have been wanting to the American student, while the introduction of many new illustrations, and the most careful mechanical execution, render the volume one of the most attractive as yet issued.

For upwards of thirteen years Dr. Carpenter's work has been considered by the profession generally, both in this country and England, as the most valuable compendium on the subject of physiology in our language. This distinction it owes to the high attainments and unwearied industry of its accomplished author. The present edition (which, like the last American one, was prepared by the author himself), is the result of such extensive revision, that it may almost be considered a new work. We need hardly say, in concluding this brief notice, that while the work is indispensable to every student of medicine in this country, it will amply repay the practitioner for its perusal by the interest and value of its contents.—*Boston Med. and Surg. Journal*.

This is a standard work—the text-book used by all medical students who read the English language. It has passed through several editions in order to keep pace with the rapidly growing science of Physiology. Nothing need be said in its praise, for its merits are universally known; we have nothing to say of its defects, for they only appear where the science of which it treats is incomplete.—*Western Lancet*.

The most complete exposition of physiology which any language can at present give.—*Brit. and For. Med.-Chirurg. Review*.

The greatest, the most reliable, and the best book on the subject which we know of in the English language.—*Stethoscope*.

To eulogize this great work would be superfluous. We should observe, however, that in this edition the author has remodelled a large portion of the former, and the editor has added much matter of interest, especially in the form of illustrations. We may confidently recommend it as the most complete work on Human Physiology in our language.—*Southern Med. and Surg. Journal*.

The most complete work on the science in our language.—*Am. Med. Journal*.

The most complete work now extant in our language.—*N. O. Med. Register*.

The best text-book in the language on this extensive subject.—*London Med. Times*.

A complete cyclopaedia of this branch of science.—*N. Y. Med. Times*.

The profession of this country, and perhaps also of Europe, have anxiously and for some time awaited the announcement of this new edition of Carpenter's Human Physiology. His former editions have for many years been almost the only text-book on Physiology in all our medical schools, and its circulation among the profession has been unsurpassed by any work in any department of medical science.

It is quite unnecessary for us to speak of this work as its merits would justify. The mere announcement of its appearance will afford the highest pleasure to every student of Physiology, while its perusal will be of infinite service in advancing physiological science.—*Ohio Med. and Surg. Journ.*

**CARPENTER (WILLIAM B.), M. D., F. R. S.,**

Examiner in Physiology and Comparative Anatomy in the University of London.

**THE MICROSCOPE AND ITS REVELATIONS.** With an Appendix containing the Applications of the Microscope to Clinical Medicine, &c. By F. G. SMITH, M. D. Illustrated by four hundred and thirty-four beautiful engravings on wood. In one large and very handsome octavo volume, of 724 pages, extra cloth, \$4 00; leather, \$4 50.

Dr. Carpenter's position as a microscopist and physiologist, and his great experience as a teacher, eminently qualify him to produce what has long been wanted—a good text-book on the practical use of the microscope. In the present volume his object has been, as stated in his Preface, “to combine, within a moderate compass, that information with regard to the use of his ‘tools,’ which is most essential to the working microscopist, with such an account of the objects best fitted for his study, as might qualify him to comprehend what he observes, and might thus prepare him to benefit science, whilst expanding and refreshing his own mind.” That he has succeeded in accomplishing this, no one acquainted with his previous labors can doubt.

The great importance of the microscope as a means of diagnosis, and the number of microscopists who are also physicians, have induced the American publishers, with the author's approval, to add an Appendix, carefully prepared by Professor Smith, on the applications of the instrument to clinical medicine, together with an account of American Microscopes, their modifications and accessories. This portion of the work is illustrated with nearly one hundred wood-cuts, and, it is hoped, will adapt the volume more particularly to the use of the American student.

Those who are acquainted with Dr. Carpenter's previous writings on Animal and Vegetable Physiology, will fully understand how vast a store of knowledge he is able to bring to bear upon so comprehensive a subject as the revelations of the microscope; and even those who have no previous acquaintance with the construction or uses of this instrument, will find abundance of information conveyed in clear and simple language.—*Med. Times and Gazette.*

Although originally not intended as a strictly

medical work, the additions by Prof. Smith give it a positive claim upon the profession, for which we doubt not he will receive their sincere thanks. Indeed, we know not where the student of medicine will find such a complete and satisfactory collection of microscopic facts bearing upon physiology and practical medicine as is contained in Prof. Smith's appendix; and this of itself, it seems to us, is fully worth the cost of the volume.—*Louisville Medical Review.*

BY THE SAME AUTHOR.

**ELEMENTS (OR MANUAL) OF PHYSIOLOGY, INCLUDING PHYSIOLOGICAL ANATOMY.** Second American, from a new and revised London edition. With one hundred and ninety illustrations. In one very handsome octavo volume, leather. pp. 566. \$3 00.

In publishing the first edition of this work, its title was altered from that of the London volume, by the substitution of the word “Elements” for that of “Manual,” and with the author's sanction the title of “Elements” is still retained as being more expressive of the scope of the treatise.

To say that it is the best manual of Physiology now before the public, would not do sufficient justice to the author.—*Buffalo Medical Journal.*

In his former works it would seem that he had exhausted the subject of Physiology. In the present, he gives the essence, as it were, of the whole.—*N. Y. Journal of Medicine.*

Those who have occasion for an elementary treatise on Physiology, cannot do better than to possess themselves of the manual of Dr. Carpenter.—*Medical Examiner.*

The best and most complete exposé of modern Physiology, in one volume, extant in the English language.—*St. Louis Medical Journal.*

BY THE SAME AUTHOR.

**PRINCIPLES OF COMPARATIVE PHYSIOLOGY.** New American, from the Fourth and Revised London edition. In one large and handsome octavo volume, with over three hundred beautiful illustrations. pp. 752. Extra cloth, \$4 80; leather, raised bands, \$5 25.

This book should not only be read but thoroughly studied by every member of the profession. None are too wise or old, to be benefited thereby. But especially to the younger class would we cordially commend it as best fitted of any work in the English language to qualify them for the reception and comprehension of those truths which are daily being developed in physiology.—*Medical Counsellor.*

Without pretending to it, it is an encyclopedia of the subject, accurate and complete in all respects—a truthful reflection of the advanced state at which the science has now arrived.—*Dublin Quarterly Journal of Medical Science.*

A truly magnificent work—in itself a perfect physiological study.—*Ranking's Abstract.*

This work stands without its fellow. It is one few men in Europe could have undertaken; it is one

no man, we believe, could have brought to so successful an issue as Dr. Carpenter. It required for its production a physiologist at once deeply read in the labors of others, capable of taking a general, critical, and unprejudiced view of those labors, and of combining the varied, heterogeneous materials at his disposal, so as to form an harmonious whole. We feel that this abstract can give the reader a very imperfect idea of the fullness of this work, and no idea of its unity, of the admirable manner in which material has been brought, from the most various sources, to conduce to its completeness, of the lucidity of the reasoning it contains, or of the clearness of language in which the whole is clothed. Not the profession only, but the scientific world at large, must feel deeply indebted to Dr. Carpenter for this great work. It must, indeed, add largely even to his high reputation.—*Medical Times.*

BY THE SAME AUTHOR. (*Preparing.*)

**PRINCIPLES OF GENERAL PHYSIOLOGY, INCLUDING ORGANIC CHEMISTRY AND HISTOLOGY.** With a General Sketch of the Vegetable and Animal Kingdom. In one large and very handsome octavo volume, with several hundred illustrations.

BY THE SAME AUTHOR.

**A PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE.** New edition, with a Preface by D. F. CONDIE, M. D., and explanations of scientific words. In one neat 12mo. volume, extra cloth. pp. 178. 50 cents.

CONDIE (D. F.), M. D., &amp;c.

**A PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.** Fifth edition, revised and augmented. In one large volume, 8vo., leather, of over 750 pages. \$3 25. (Just Issued, 1859.)

In presenting a new and revised edition of this favorite work, the publishers have only to state that the author has endeavored to render it in every respect "a complete and faithful exposition of the pathology and therapeutics of the maladies incident to the earlier stages of existence—a full and exact account of the diseases of infancy and childhood." To accomplish this he has subjected the whole work to a careful and thorough revision, rewriting a considerable portion, and adding several new chapters. In this manner it is hoped that any deficiencies which may have previously existed have been supplied, that the recent labors of practitioners and observers have been thoroughly incorporated, and that in every point the work will be found to maintain the high reputation it has enjoyed as a complete and thoroughly practical book of reference in infantile affections.

A few notices of previous editions are subjoined.

Dr. Condie's scholarship, acumen, industry, and practical sense are manifested in this, as in all his numerous contributions to science.—*Dr. Holmes's Report to the American Medical Association.*

Taken as a whole, in our judgment, Dr. Condie's Treatise is the one from the perusal of which the practitioner in this country will rise with the greatest satisfaction.—*Western Journal of Medicine and Surgery.*

One of the best works upon the Diseases of Children in the English language.—*Western Lancet.*

We feel assured from actual experience that no physician's library can be complete without a copy of this work.—*N. Y. Journal of Medicine.*

A veritable pædiatric encyclopædia, and an honor to American medical literature.—*Ohio Medical and Surgical Journal.*

We feel persuaded that the American medical profession will soon regard it not only as a very good, but as the VERY BEST "Practical Treatise on the Diseases of Children."—*American Medical Journal.*

In the department of infantile therapeutics, the work of Dr. Condie is considered one of the best which has been published in the English language.—*The Stethoscope.*

We pronounced the first edition to be the best work on the diseases of children in the English language, and, notwithstanding all that has been published, we still regard it in that light.—*Medical Examiner.*

The value of works by native authors on the diseases which the physician is called upon to combat, will be appreciated by all; and the work of Dr. Condie has gained for itself the character of a safe guide for students, and a useful work for consultation by those engaged in practice.—*N. Y. Med. Times.*

This is the fourth edition of this deservedly popular treatise. During the interval since the last edition, it has been subjected to a thorough revision by the author; and all new observations in the pathology and therapeutics of children have been included in the present volume. As we said before, we do not know of a better book on diseases of children, and to a large part of its recommendations we yield an unhesitating concurrence.—*Buffalo Med. Journal.*

Perhaps the most full and complete work now before the profession of the United States; indeed, we may say in the English language. It is vastly superior to most of its predecessors.—*Transylvania Med. Journal.*

CHRISTISON (ROBERT), M. D., V. P. R. S. E., &amp;c.

**A DISPENSATORY; or, Commentary on the Pharmacopœias of Great Britain and the United States;** comprising the Natural History, Description, Chemistry, Pharmacy, Actions, Uses, and Doses of the Articles of the Materia Medica. Second edition, revised and improved, with a Supplement containing the most important New Remedies. With copious Additions, and two hundred and thirteen large wood-engravings. By R. EGLESFELD GRIFFITH, M. D. In one very large and handsome octavo volume, leather, raised bands, of over 1000 pages. \$3 50.

COOPER (BRANSBY B.), F. R. S.

**LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY.**

In one very large octavo volume, extra cloth, of 750 pages. \$3 00.

**COOPER ON DISLOCATIONS AND FRACTURES OF THE JOINTS.**—Edited by BRANSBY B. COOPER, F. R. S., &c. With additional Observations by Prof. J. C. WARREN. A new American edition. In one handsome octavo volume, extra cloth, of about 500 pages, with numerous illustrations on wood. \$3 25.

**COOPER ON THE ANATOMY AND DISEASES OF THE BREAST,** with twenty-five Miscellaneous and Surgical Papers. One large volume, imperial 8vo., extra cloth, with 252 figures, on 36 plates. \$2 50.

**COOPER ON THE STRUCTURE AND DISEASES OF THE TESTIS, AND ON THE THYMUS GLAND.** One vol. imperial 8vo., extra cloth, with 177 figures on 29 plates. \$2 00.

**COPLAND ON THE CAUSES, NATURE, AND TREATMENT OF PALSY AND APOPLEXY.** In one volume, royal 12mo., extra cloth. pp. 326. 80 cents.

**CLYMER ON FEVERS; THEIR DIAGNOSIS, PATHOLOGY, AND TREATMENT.** In one octavo volume, leather, of 600 pages. \$1 50.

**COLOMBAT DE L'ISERE ON THE DISEASES OF FEMALES,** and on the special Hygiene of their Sex. Translated, with many Notes and Additions, by C. D. MORGAN, M. D. Second edition, revised and improved. In one large volume, octavo, leather, with numerous wood-cuts. pp. 720. \$3 50.

CARSON (JOSEPH), M. D.,

Professor of Materia Medica and Pharmacy in the University of Pennsylvania.

**SYNOPSIS OF THE COURSE OF LECTURES ON MATERIA MEDICA AND PHARMACY,** delivered in the University of Pennsylvania. Second and revised edition. In one very neat octavo volume, extra cloth, of 208 pages. \$1 50.

CURLING (T. B.), F. R. S.,

Surgeon to the London Hospital, President of the Hunterian Society, &c.

**A PRACTICAL TREATISE ON DISEASES OF THE TESTIS, SPERMATIC CORD, AND SCROTUM.** Second American, from the second and enlarged English edition. In one handsome octavo volume, extra cloth, with numerous illustrations. pp. 420. \$2 00.

CHURCHILL (FLEETWOOD), M. D., M. R. I. A.

**ON THE THEORY AND PRACTICE OF MIDWIFERY.** A new American from the fourth revised and enlarged London edition. With Notes and Additions, by D. FRANCIS CONDIE, M. D., author of a "Practical Treatise on the Diseases of Children," &c. With 194 illustrations. In one very handsome octavo volume, leather, of nearly 700 large pages. \$3 50. (Just Issued.)

This work has been so long an established favorite, both as a text-book for the learner and as a reliable aid in consultation for the practitioner, that in presenting a new edition it is only necessary to call attention to the very extended improvements which it has received. Having had the benefit of two revisions by the author since the last American reprint, it has been materially enlarged, and Dr. Churchill's well-known conscientious industry is a guarantee that every portion has been thoroughly brought up with the latest results of European investigation in all departments of the science and art of obstetrics. The recent date of the last Dublin edition has not left much of novelty for the American editor to introduce, but he has endeavored to insert whatever has since appeared, together with such matters as his experience has shown him would be desirable for the American student, including a large number of illustrations. With the sanction of the author he has added in the form of an appendix, some chapters from a little "Manual for Midwives and Nurses," recently issued by Dr. Churchill, believing that the details there presented can hardly fail to prove of advantage to the junior practitioner. The result of all these additions is that the work now contains fully one-half more matter than the last American edition, with nearly one-half more illustrations, so that notwithstanding the use of a smaller type, the volume contains almost two hundred pages more than before.

No effort has been spared to secure an improvement in the mechanical execution of the work equal to that which the text has received, and the volume is confidently presented as one of the handsomest that has thus far been laid before the American profession; while the very low price at which it is offered should secure for it a place in every lecture-room and on every office table.

A better book in which to learn these important points we have not met than Dr. Churchill's. Every page of it is full of instruction; the opinion of all writers of authority is given on questions of difficulty, as well as the directions and advice of the learned author himself, to which he adds the result of statistical inquiry, putting statistics in their proper place and giving them their due weight, and no more. We have never read a book more free from professional jealousy than Dr. Churchill's. It appears to be written with the true design of a hook on medicine, viz: to give all that is known on the subject of which he treats, both theoretically and practically, and to advance such opinions of his own as he believes will benefit medical science, and insure the safety of the patient. We have said enough to convey to the profession that this book of Dr. Churchill's is admirably suited for a book of reference for the practitioner, as well as a text-book for the student, and we hope it may be extensively purchased amongst our readers. To them we most strongly recommend it.—*Dublin Medical Press*, June 20, 1860.

To bestow praise on a book that has received such marked approbation would be superfluous. We need only say, therefore, that if the first edition was thought worthy of a favorable reception by the medical public, we can confidently affirm that this will be found much more so. The lecturer, the practitioner, and the student, may all have recourse to its pages, and derive from their perusal much interest and instruction in everything relating to theoretical and practical midwifery.—*Dublin Quarterly Journal of Medical Sciences*.

A work of very great merit, and such as we can confidently recommend to the study of every obstetric practitioner.—*London Medical Gazette*.

This is certainly the most perfect system extant. It is the best adapted for the purposes of a text-book, and that which he whose necessities confine him to one book, should select in preference to all others.—*Southern Medical and Surgical Journal*.

BY THE SAME AUTHOR. (Lately Published.)

**ON THE DISEASES OF INFANTS AND CHILDREN.** Second American Edition, revised and enlarged by the author. Edited, with Notes, by W. V. KEATING, M. D. In one large and handsome volume, extra cloth, of over 700 pages. \$3 00, or in leather, \$3 25.

In preparing this work a second time for the American profession, the author has spared no labor in giving it a very thorough revision, introducing several new chapters, and rewriting others, while every portion of the volume has been subjected to a severe scrutiny. The efforts of the American editor have been directed to supplying such information relative to matters peculiar to this country as might have escaped the attention of the author, and the whole may, therefore, be safely pronounced one of the most complete works on the subject accessible to the American Profession. By an alteration in the size of the page, these very extensive additions have been accommodated without unduly increasing the size of the work.

BY THE SAME AUTHOR.

**ESSAYS ON THE PUERPERAL FEVER, AND OTHER DISEASES PECULIAR TO WOMEN.** Selected from the writings of British Authors previous to the close of the Eighteenth Century. In one neat octavo volume, extra cloth, of about 450 pages. \$2 50.

The most popular work on midwifery ever issued from the American press.—*Charleston Med. Journal*.

We were reduced to the necessity of having but one work on midwifery, and permitted to choose, we would unhesitatingly take Churchill.—*Western Med. and Surg. Journal*.

It is impossible to conceive a more useful and elegant manual than Dr. Churchill's Practice of Midwifery.—*Provincial Medical Journal*.

Certainly, in our opinion, the very best work on the subject which exists.—*N. Y. Analyst*.

No work holds a higher position, or is more deserving of being placed in the hands of the tyro, the advanced student, or the practitioner.—*Medical Examiner*.

Previous editions, under the editorial supervision of Prof R. M. Huston, have been received with marked favor, and they deserved it; but this, reprinted from a very late Dublin edition, carefully revised and brought up by the author to the present time, does present an unusually accurate and able exposition of every important particular embraced in the department of midwifery. \* The clearness, directness, and precision of its teachings, together with the great amount of statistical research which its text exhibits, have served to place it already in the foremost rank of works in this department of remedial science.—*N. O. Med. and Surg. Journal*.

In our opinion, it forms one of the best if not the very best text-book and epitome of obstetric science which we at present possess in the English language.—*Monthly Journal of Medical Science*.

The clearness and precision of style in which it is written, and the great amount of statistical research which it contains, have served to place it in the first rank of works in this department of medical science.—*N. Y. Journal of Medicine*.

Few treatises will be found better adapted as a text-book for the student, or as a manual for the frequent consultation of the young practitioner.—*American Medical Journal*.

(Lately Published.)

**CHURCHILL (FLEETWOOD), M. D., M. R. I. A., &c.**  
**ON THE DISEASES OF WOMEN;** including those of Pregnancy and Child-bed. A new American edition, revised by the Author. With Notes and Additions, by D. FRANCIS CONDIE, M. D., author of "A Practical Treatise on the Diseases of Children." With numerous illustrations. In one large and handsome octavo volume, leather, of 768 pages. \$3 00.

This edition of Dr. Churchill's very popular treatise may almost be termed a new work, so thoroughly has he revised it in every portion. It will be found greatly enlarged, and completely brought up to the most recent condition of the subject, while the very handsome series of illustrations introduced, representing such pathological conditions as can be accurately portrayed, present a novel feature, and afford valuable assistance to the young practitioner. Such additions as appeared desirable for the American student have been made by the editor, Dr. Condie, while a marked improvement in the mechanical execution keeps pace with the advance in all other respects which the volume has undergone, while the price has been kept at the former very moderate rate.

It comprises, unquestionably, one of the most exact and comprehensive expositions of the present state of medical knowledge in respect to the diseases of women that has yet been published.—*Am. Journ. Med. Sciences.*

This work is the most reliable which we possess on this subject; and is deservedly popular with the profession.—*Charleston Med. Journal*, July, 1857.

We know of no author who deserves that approbation, on "the diseases of females," to the same

extent that Dr. Churchill does. His, indeed, is the only thorough treatise we know of on the subject; and it may be commended to practitioners and students as a masterpiece in its particular department.—*The Western Journal of Medicine and Surgery.*

As a comprehensive manual for students, or a work of reference for practitioners, it surpasses any other that has ever issued on the same subject from the British press.—*Dublin Quart. Journal.*

**DICKSON (S. H.), M. D.,**

Professor of Practice of Medicine in the Jefferson Medical College, Philadelphia.

**ELEMENTS OF MEDICINE;** a Compendious View of Pathology and Therapeutics, or the History and Treatment of Diseases. Second edition, revised. In one large and handsome octavo volume. of 750 pages, leather. \$3 75. (*Just Issued.*)

The steady demand which has so soon exhausted the first edition of this work, sufficiently shows that the author was not mistaken in supposing that a volume of this character was needed—an elementary manual of practice, which should present the leading principles of medicine with the practical results, in a condensed and perspicuous manner. Disencumbered of unnecessary detail and fruitless speculations, it embodies what is most requisite for the student to learn, and at the same time what the active practitioner wants when obliged, in the daily calls of his profession, to refresh his memory on special points. The clear and attractive style of the author renders the whole easy of comprehension, while his long experience gives to his teachings an authority everywhere acknowledged. Few physicians, indeed, have had wider opportunities for observation and experience, and few, perhaps, have used them to better purpose. As the result of a long life devoted to study and practice, the present edition, revised and brought up to the date of publication, will doubtless maintain the reputation already acquired as a condensed and convenient American text-book on the Practice of Medicine.

**DRUITT (ROBERT), M. R. C. S., &c.**

**THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.** A new and revised American from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood-engravings. In one very handsomely printed octavo volume, leather, of nearly 700 large pages. \$3 50. (*Just Issued.*)

A work which like DRUITT'S SURGERY has for so many years maintained the position of a leading favorite with all classes of the profession, needs no special recommendation to attract attention to a revised edition. It is only necessary to state that the author has spared no pains to keep the work up to its well earned reputation of presenting in a small and convenient compass the latest condition of every department of surgery, considered both as a science and as an art; and that the services of a competent American editor have been employed to introduce whatever novelties may have escaped the author's attention, or may prove of service to the American practitioner. As several editions have appeared in London since the issue of the last American reprint, the volume has had the benefit of repeated revisions by the author, resulting in a very thorough alteration and improvement. The extent of these additions may be estimated from the fact that it now contains about one-third more matter than the previous American edition, and that notwithstanding the adoption of a smaller type, the pages have been increased by about one hundred, while nearly two hundred and fifty wood-cuts have been added to the former list of illustrations.

A marked improvement will also be perceived in the mechanical and artistic execution of the work, which, printed in the best style, on new type, and fine paper, leaves little to be desired as regards external finish; while at the very low price affixed it will be found one of the cheapest volumes accessible to the profession.

This popular volume, now a most comprehensive work on surgery, has undergone many corrections, improvements, and additions, and the principles and the practice of the art have been brought down to the latest record and observation. Of the operations in surgery it is impossible to speak too highly. The descriptions are so clear and concise, and the illustrations so accurate and numerous, that the student can have no difficulty, with instrument in hand, and book by his side, over the dead body, in obtaining a proper knowledge and sufficient tact in this much neglected department of medical education.—*British and Foreign Medico-Chirurg. Review*, Jan. 1860.

In the present edition the author has entirely rewritten many of the chapters, and has incorporated the various improvements and additions in modern surgery. On carefully going over it, we find that

nothing of real practical importance has been omitted; it presents a faithful epitome of everything relating to surgery up to the present hour. It is deservedly a popular manual, both with the student and practitioner.—*London Lancet*, Nov. 19, 1859.

In closing this brief notice, we recommend as cordially as ever this most useful and comprehensive hand-book. It must prove a vast assistance, not only to the student of surgery, but also to the busy practitioner who may not have the leisure to devote himself to the study of more lengthy volumes.—*London Med. Times and Gazette*, Oct. 22, 1859.

In a word, this eighth edition of Dr. Drutt's Manual of Surgery is all that the surgical student or practitioner could desire.—*Dublin Quarterly Journal of Med. Sciences*, Nov. 1859.

## DALTON, JR. (J. C.), M. D.

Professor of Physiology in the College of Physicians, New York.

**A TREATISE ON HUMAN PHYSIOLOGY**, designed for the use of Students and Practitioners of Medicine. Second edition, revised and enlarged, with two hundred and seventy-one illustrations on wood. In one very beautiful octavo volume, of 700 pages, extra cloth, \$4 00; leather, raised bands, \$4 50. (*Just Issued*, 1861.)

The general favor which has so soon exhausted an edition of this work has afforded the author an opportunity in its revision of supplying the deficiencies which existed in the former volume. This has caused the insertion of two new chapters—one on the Special Senses, the other on Imbibition, Exhalation, and the Functions of the Lymphatic System—besides numerous additions of smaller amount scattered through the work, and a general revision designed to bring it thoroughly up to the present condition of the science with regard to all points which may be considered as definitely settled. A number of new illustrations has been introduced, and the work, it is hoped, in its improved form, may continue to command the confidence of those for whose use it is intended.

It will be seen, therefore, that Dr. Dalton's best efforts have been directed towards perfecting his work. The additions are marked by the same features which characterize the remainder of the volume, and render it by far the most desirable text-book on physiology to place in the hands of the student which, so far as we are aware, exists in the English language, or perhaps in any other. We therefore have no hesitation in recommending Dr. Dalton's book for the classes for which it is intended, satisfied as we are that it is better adapted to their use than any other work of the kind to which they have access.—*American Journal of the Medical Sciences*, April, 1861.

It is, therefore, no disparagement to the many books upon physiology, most excellent in their day, to say that Dalton's is the only one that gives us the science as it was known to the best philosophers throughout the world, at the beginning of the current year. It states in comprehensive but concise diction, the facts established by experiment, or other method of demonstration, and details, in an understandable manner, how it is done, but abstains from the discussion of unsettled or theoretical points. Herein it is unique; and these characteristics render it a text-book without a rival, for those who desire to study physiological science as it is known to its most successful cultivators. And it is physiology thus presented that lies at the foundation of correct pathological knowledge; and this in turn is the basis of rational therapeutics; so that pathology, in fact, becomes of prime importance in the proper discharge of our every-day practical duties.—*Cincinnati Lancet*, May, 1861.

Dr. Dalton needs no word of praise from us. He is universally recognized as among the first, if not the very first, of American physiologists now living. The first edition of his admirable work appeared but two years since, and the advance of science, his

own original views and experiments, together with a desire to supply what he considered some deficiencies in the first edition, have already made the present one a necessity, and it will no doubt be even more eagerly sought for than the first. That it is not merely a reprint, will be seen from the author's statement of the following principal additions and alterations which he has made. The present, like the first edition, is printed in the highest style of the printer's art, and the illustrations are truly admirable for their clearness in expressing exactly what their author intended.—*Boston Medical and Surgical Journal*, March 28, 1861.

It is unnecessary to give a detail of the additions; suffice it to say, that they are numerous and important, and such as will render the work still more valuable and acceptable to the profession as a learned and original treatise on this all-important branch of medicine. All that was said in commendation of the getting up of the first edition, and the superior style of the illustrations, apply with equal force to this. No better work on physiology can be placed in the hand of the student.—*St. Louis Medical and Surgical Journal*, May, 1861.

These additions, while testifying to the learning and industry of the author, render the book exceedingly useful, as the most complete exposé of a science, of which Dr. Dalton is doubtless the ablest representative on this side of the Atlantic.—*New Orleans Med. Times*, May, 1861.

A second edition of this deservedly popular work having been called for in the short space of two years, the author has supplied deficiencies, which existed in the former volume, and has thus more completely fulfilled his design of presenting to the profession a reliable and precise text-book, and one which we consider the best outline on the subject of which it treats, in any language.—*N. American Medico-Chirurg. Review*, May, 1861.

## DUNGLISON, FORBES, TWEEDIE, AND CONOLLY.

**THE CYCLOPÆDIA OF PRACTICAL MEDICINE**: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica, and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, &c. &c. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound, with raised bands. \$12 00.

\*\*\* This work contains no less than four hundred and eighteen distinct treatises, contributed by sixty-eight distinguished physicians, rendering it a complete library of reference for the country practitioner.

The most complete work on Practical Medicine extant; or, at least, in our language.—*Buffalo Medical and Surgical Journal*.

For reference, it is above all price to every practitioner.—*Western Lancet*.

One of the most valuable medical publications of the day—as a work of reference it is invaluable.—*Western Journal of Medicine and Surgery*.

It has been to us, both as learner and teacher, a work for ready and frequent reference, one in which modern English medicine is exhibited in the most advantageous light.—*Medical Examiner*.

The editors are practitioners of established reputation, and the list of contributors embraces many of the most eminent professors and teachers of London, Edinburgh, Dublin, and Glasgow. It is, indeed, the great merit of this work that the principal articles have been furnished by practitioners who have not only devoted especial attention to the diseases about which they have written, but have also enjoyed opportunities for an extensive practical acquaintance with them and whose reputation carries the assurance of their competency justly to appreciate the opinions of others, while it stamps their own doctrines with high and just authority.—*American Medical Journal*.

**DEWEES'S COMPREHENSIVE SYSTEM OF MIDWIFERY**. Illustrated by occasional cases and many engravings. Twelfth edition, with the author's last improvements and corrections. In one octavo volume, extra cloth, of 600 pages. \$3 20.

**DEWEES'S TREATISE ON THE PHYSICAL**

**AND MEDICAL TREATMENT OF CHILDREN**. The last edition. In one volume, octavo, extra cloth, 548 pages. \$2 80

**DEWEES'S TREATISE ON THE DISEASES OF FEMALES**. Tenth edition. In one volume, octavo extra cloth, 532 pages, with plates. \$3 00

DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

NEW AND ENLARGED EDITION.

**MEDICAL LEXICON;** a Dictionary of Medical Science, containing a concise Explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, Dentistry, &c. Notices of Climate and of Mineral Waters; Formulæ for Official, Empirical, and Dietetic Preparations, &c. With French and other Synonymes. Revised and very greatly enlarged. In one very large and handsome octavo volume, of 992 double-columned pages, in small type; strongly bound in leather, with raised bands. Price \$4 00.

Especial care has been devoted in the preparation of this edition to render it in every respect worthy a continuance of the very remarkable favor which it has hitherto enjoyed. The rapid sale of FIFTEEN large editions, and the constantly increasing demand, show that it is regarded by the profession as the standard authority. Stimulated by this fact, the author has endeavored in the present revision to introduce whatever might be necessary "to make it a satisfactory and desirable—if not indispensable—lexicon, in which the student may search without disappointment for every term that has been legitimated in the nomenclature of the science." To accomplish this, large additions have been found requisite, and the extent of the author's labors may be estimated from the fact that about SIX THOUSAND subjects and terms have been introduced throughout, rendering the whole number of definitions about SIXTY THOUSAND, to accommodate which, the number of pages has been increased by nearly a hundred, notwithstanding an enlargement in the size of the page. The medical press, both in this country and in England, has pronounced the work indispensable to all medical students and practitioners, and the present improved edition will not lose that enviable reputation.

The publishers have endeavored to render the mechanical execution worthy of a volume of such universal use in daily reference. The greatest care has been exercised, to obtain the typographical accuracy so necessary in a work of the kind. By the small but exceedingly clear type employed, an immense amount of matter is condensed in its thousand ample pages, while the binding will be found strong and durable. With all these improvements and enlargements, the price has been kept at the former very moderate rate, placing it within the reach of all.

This work, the appearance of the fifteenth edition of which, it has become our duty and pleasure to announce, is perhaps the most stupendous monument of labor and erudition in medical literature. One would hardly suppose after constant use of the preceding editions, where we have never failed to find a sufficiently full explanation of every medical term, that in this edition "about six thousand subjects and terms have been added," with a careful revision and correction of the entire work. It is only necessary to announce the advent of this edition to make it occupy the place of the preceding one on the table of every medical man, as it is without doubt the best and most comprehensive work of the kind which has ever appeared.—*Buffalo Med. Journ.*, Jan. 1853.

The work is a monument of patient research, skilful judgment, and vast physical labor, that will perpetuate the name of the author more effectually than any possible device of stone or metal. Dr. Dunglison deserves the thanks not only of the American profession, but of the whole medical world.—*North Am. Medico-Chir. Review*, Jan. 1853.

A Medical Dictionary better adapted for the wants of the profession than any other with which we are acquainted, and of a character which places it far above comparison and competition.—*Am. Journ. Med. Sciences*, Jan. 1853.

We need only say, that the addition of 6,000 new terms, with their accompanying definitions, may be said to constitute a new work, by itself. We have examined the Dictionary attentively, and are most happy to pronounce it unrivalled of its kind. The erudition displayed, and the extraordinary industry which must have been demanded, in its preparation and perfection, redound to the lasting credit of its author, and have furnished us with a volume indispensable at the present day, to all who would find themselves *au niveau* with the highest standards of medical information.—*Boston Medical and Surgical Journal*, Dec. 31, 1857.

Good lexicons and encyclopedic works generally, are the most labor-saving contrivances which literary men enjoy; and the labor which is required to produce them in the perfect manner of this example is something appalling to contemplate. The author

tells us in his preface that he has added about six thousand terms and subjects to this edition, which, before, was considered universally as the best work of the kind in any language.—*Silliman's Journal*, March, 1853.

He has razed his gigantic structure to the foundations, and remodelled and reconstructed the entire pile. No less than six thousand additional subjects and terms are illustrated and analyzed in this new edition, swelling the grand aggregate to beyond sixty thousand! Thus is placed before the profession a complete and thorough exponent of medical terminology, without rival or possibility of rivalry.—*Nashville Journ. of Med. and Surg.*, Jan. 1853.

It is universally acknowledged, we believe, that this work is incomparably the best and most complete Medical Lexicon in the English language. The amount of labor which the distinguished author has bestowed upon it is truly wonderful, and the learning and research displayed in its preparation are equally remarkable. Comment and commendation are unnecessary, as no one at the present day thinks of purchasing any other Medical Dictionary than this.—*St. Louis Med. and Surg. Journ.*, Jan. 1853.

It is the foundation stone of a good medical library, and should always be included in the first list of books purchased by the medical student.—*Am. Med. Monthly*, Jan. 1853.

A very perfect work of the kind, undoubtedly the most perfect in the English language.—*Med. and Surg. Reporter*, Jan. 1853.

It is now emphatically the Medical Dictionary of the English language, and for it there is no substitute.—*N. H. Med. Journ.*, Jan. 1853.

It is scarcely necessary to remark that any medical library wanting a copy of Dunglison's Lexicon must be imperfect.—*Cin. Lancet*, Jan. 1853.

We have ever considered it the best authority published, and the present edition we may safely say has no equal in the world.—*Peninsular Med. Journal*, Jan. 1853.

The most complete authority on the subject to be found in any language.—*Va. Med. Journal*, Feb. '53.

BY THE SAME AUTHOR.

**THE PRACTICE OF MEDICINE.** A Treatise on Special Pathology and Therapeutics. Third Edition. In two large octavo volumes, leather, of 1,500 pages. \$5 25.

## DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

**HUMAN PHYSIOLOGY.** Eighth edition. Thoroughly revised and extensively modified and enlarged, with five hundred and thirty-two illustrations. In two large and handsomely printed octavo volumes, leather, of about 1500 pages. \$7 00.

In revising this work for its eighth appearance, the author has spared no labor to render it worthy a continuance of the very great favor which has been extended to it by the profession. The whole contents have been rearranged, and to a great extent remodelled; the investigations which of late years have been so numerous and so important, have been carefully examined and incorporated, and the work in every respect has been brought up to a level with the present state of the subject. The object of the author has been to render it a concise but comprehensive treatise, containing the whole body of physiological science, to which the student and man of science can at all times refer with the certainty of finding whatever they are in search of, fully presented in all its aspects; and on no former edition has the author bestowed more labor to secure this result.

We believe that it can truly be said, no more complete repository of facts upon the subject treated, can anywhere be found. The author has, moreover, that enviable tact at description and that facility and ease of expression which render him peculiarly acceptable to the casual, or the studious reader. This faculty, so requisite in setting forth many graver and less attractive subjects, lends additional charms to one always fascinating.—*Boston Med. and Surg. Journal*.

The most complete and satisfactory system of Physiology in the English language.—*Amer. Med. Journal*.

The best work of the kind in the English language.—*Silliman's Journal*.

The present edition the author has made a perfect mirror of the science as it is at the present hour. As a work upon physiology proper, the science of the functions performed by the body, the student will find it all he wishes.—*Nashville Journ. of Med.*

That he has succeeded, most admirably succeeded in his purpose, is apparent from the appearance of an eighth edition. It is now the great encyclopædia on the subject, and worthy of a place in every physician's library.—*Western Lancet*.

BY THE SAME AUTHOR. (*A new edition.*)

**GENERAL THERAPEUTICS AND MATERIA MEDICA;** adapted for a Medical Text-book. With Indexes of Remedies and of Diseases and their Remedies. SIXTH EDITION, revised and improved. With one hundred and ninety-three illustrations. In two large and handsomely printed octavo vols., leather, of about 1100 pages. \$6 00.

In announcing a new edition of Dr. Dunglison's General Therapeutics and Materia Medica, we have no words of commendation to bestow upon a work whose merits have been heretofore so often and so justly extolled. It must not be supposed, however, that the present is a mere reprint of the previous edition; the character of the author for laborious research, judicious analysis, and clearness of expression, is fully sustained by the numerous additions he has made to the work, and the careful revision to which he has subjected the whole.—*N. A. Medico-Chir. Review*, Jan. 1858.

The work will, we have little doubt, be bought and read by the majority of medical students; its size, arrangement, and reliability recommend it to all; no one, we venture to predict, will study it without profit, and there are few to whom it will not be in some measure useful as a work of reference. The young practitioner, more especially, will find the copious indexes appended to this edition of great assistance in the selection and preparation of suitable formulæ.—*Charleston Med. Journ. and Review*, Jan. 1858.

BY THE SAME AUTHOR. (*A new Edition.*)

**NEW REMEDIES, WITH FORMULÆ FOR THEIR PREPARATION AND ADMINISTRATION.** Seventh edition, with extensive Additions. In one very large octavo volume, leather, of 770 pages. \$3 75.

Another edition of the "New Remedies" having been called for, the author has endeavored to add everything of moment that has appeared since the publication of the last edition.

The articles treated of in the former editions will be found to have undergone considerable expansion in this, in order that the author might be enabled to introduce, as far as practicable, the results of the subsequent experience of others, as well as of his own observation and reflection; and to make the work still more deserving of the extended circulation with which the preceding editions have been favored by the profession. By an enlargement of the page, the numerous additions have been incorporated without greatly increasing the bulk of the volume.—*Preface*.

One of the most useful of the author's works.—*Southern Medical and Surgical Journal*.

This elaborate and useful volume should be found in every medical library, for as a book of reference, for physicians, it is unsurpassed by any other work in existence, and the double index for diseases and for remedies, will be found greatly to enhance its value.—*New York Med. Gazette*.

The great learning of the author, and his remarkable industry in pushing his researches into every source whence information is derivable, have enabled him to throw together an extensive mass of facts and statements, accompanied by full reference to authorities; which last feature renders the work practically valuable to investigators who desire to examine the original papers.—*The American Journal of Pharmacy*.

ELLIS (BENJAMIN), M. D.

**THE MEDICAL FORMULARY:** being a Collection of Prescriptions, derived from the writings and practice of many of the most eminent physicians of America and Europe. Together with the usual Dietetic Preparations and Antidotes for Poisons. To which is added an Appendix, on the Endermic use of Medicines, and on the use of Ether and Chloroform. The whole accompanied with a few brief Pharmaceutical and Medical Observations. Eleventh edition, revised and much extended by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. (*Preparing.*)

## ERICHSEN (JOHN),

Professor of Surgery in University College, London, &amp;c.

**THE SCIENCE AND ART OF SURGERY; BEING A TREATISE ON SURGICAL INJURIES, DISEASES, AND OPERATIONS.** New and improved American, from the second enlarged and carefully revised London edition. Illustrated with over four hundred engravings on wood. In one large and handsome octavo volume, of one thousand closely printed pages, leather, raised bands. \$4 50. (*Just Issued.*)

The very distinguished favor with which this work has been received on both sides of the Atlantic has stimulated the author to render it even more worthy of the position which it has so rapidly attained as a standard authority. Every portion has been carefully revised, numerous additions have been made, and the most watchful care has been exercised to render it a complete exponent of the most advanced condition of surgical science. In this manner the work has been enlarged by about a hundred pages, while the series of engravings has been increased by more than a hundred, rendering it one of the most thoroughly illustrated volumes before the profession. The additions of the author having rendered unnecessary most of the notes of the former American editor, but little has been added in this country; some few notes and occasional illustrations have, however, been introduced to elucidate American modes of practice.

It is, in our humble judgment, decidedly the best book of the kind in the English language. Strange that just such books are no oftener produced by public teachers of surgery in this country and Great Britain. Indeed, it is a matter of great astonishment, but no less true than astonishing, that of the many works on surgery republished in this country within the last fifteen or twenty years as text-books for medical students, this is the only one that even approximates to the fulfilment of the peculiar wants of young men just entering upon the study of this branch of the profession.—*Western Jour. of Med. and Surgery.*

Its value is greatly enhanced by a very copious well-arranged index. We regard this as one of the most valuable contributions to modern surgery. To one entering his novitiate of practice, we regard it the most serviceable guide which he can consult. He will find a fulness of detail leading him through every

step of the operation, and not deserting him until the final issue of the case is decided.—*Sethoscope.*

Embracing, as will be perceived, the whole surgical domain, and each division of itself almost complete and perfect, each chapter full and explicit, each subject faithfully exhibited, we can only express our estimate of it in the aggregate. We consider it an excellent contribution to surgery, as probably the best single volume now extant on the subject, and with great pleasure we add it to our text-books.—*Nashville Journal of Medicine and Surgery.*

Prof. Erichsen's work, for its size, has not been surpassed; his nine hundred and eight pages, profusely illustrated, are rich in physiological, pathological, and operative suggestions, doctrines, details, and processes; and will prove a reliable resource for information, both to physician and surgeon, in the hour of peril.—*N. O. Med. and Surg. Journal.*

## FLINT (AUSTIN), M. D.,

Professor of the Theory and Practice of Medicine in the University of Louisville, &amp;c.

**PHYSICAL EXPLORATION AND DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.** In one large and handsome octavo volume, extra cloth, 636 pages. \$3 00.

We regard it, in point both of arrangement and of the marked ability of its treatment of the subjects, as destined to take the first rank in works of this class. So far as our information extends, it has at present no equal. To the practitioner, as well as the student, it will be invaluable in clearing up the diagnosis of doubtful cases, and in shedding light upon difficult phenomena.—*Buffalo Med. Journal.*

A work of original observation of the highest merit. We recommend the treatise to every one who wishes to become a correct auscultator. Based to a very large extent upon cases numerically examined, it carries the evidence of careful study and discrimination upon every page. It does credit to the author, and, through him, to the profession in this country. It is, what we cannot call every book upon auscultation, a readable book.—*Am. Jour. Med. Sciences.*

BY THE SAME AUTHOR. (*Now Ready.*)

**A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.** In one neat octavo volume, of about 500 pages, extra cloth. \$2 75.

We do not know that Dr. Flint has written anything which is not first rate; but this, his latest contribution to medical literature, in our opinion, surpasses all the others. The work is most comprehensive in its scope, and most sound in the views it enunciates. The descriptions are clear and methodical; the statements are substantiated by facts, and are made with such simplicity and sincerity, that without them they would carry conviction. The style is admirably clear, direct, and free from dryness. With Dr. Walshe's excellent treatise before us, we have no hesitation in saying that Dr. Flint's book is the best work on the heart in the English language.—*Boston Med. and Surg. Journal.*

We have thus endeavored to present our readers with a fair analysis of this remarkable work. Preferring to employ the very words of the distinguished author, wherever it was possible, we have essayed to condense into the briefest space a general view of his observations and suggestions, and to direct the attention of our brethren to the abounding stores of valuable matter here collected and arranged for their use and instruction. No medical library will hereafter be considered complete without this volume; and we trust it will promptly find its way into the hands of every American student and physician.—*N. Am. Med. Chir. Review.*

This last work of Prof. Flint will add much to his previous well-earned celebrity, as a writer of

great force and beauty, and, with his previous work, places him at the head of American writers upon diseases of the chest. We have adopted his work upon the heart as a text-book, believing it to be more valuable for that purpose than any work of the kind that has yet appeared.—*Nashville Med. Journ.*

With more than pleasure do we hail the advent of this work, for it fills a wide gap on the list of text-books for our schools, and is, for the practitioner, the most valuable practical work of its kind.—*N. O. Med. News.*

In regard to the merits of the work, we have no hesitation in pronouncing it full, accurate, and judicious. Considering the present state of science, such a work was much needed. It should be in the hands of every practitioner.—*Chicago Med. Journal.*

But these are very trivial spots, and in no wise prevent us from declaring our most hearty approval of the author's ability, industry, and conscientiousness.—*Dublin Quarterly Journal of Med. Sciences.*

He has labored on with the same industry and care, and his place among the first authors of our country is becoming fully established. To this end, the work whose title is given above, contributes in no small degree. Our space will not admit of an extended analysis, and we will close this brief notice by commending it without reserve to every class of readers in the profession.—*Peninsular Med. Journ.*

FOWNES (GEORGE), PH. D., &amp;c.

**A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.**

From the seventh revised and corrected London edition. With one hundred and ninety-seven illustrations. Edited by ROBERT BRIDGES, M. D. In one large royal 12mo. volume, of 600 pages. In leather, \$1 65; extra cloth, \$1 50. (*Just Issued.*)

The death of the author having placed the editorial care of this work in the practised hands of Drs. Bence Jones and A. W. Hoffman, everything has been done in its revision which experience could suggest to keep it on a level with the rapid advance of chemical science. The additions requisite to this purpose have necessitated an enlargement of the page, notwithstanding which the work has been increased by about fifty pages. At the same time every care has been used to maintain its distinctive character as a condensed manual for the student, divested of all unnecessary detail or mere theoretical speculation. The additions have, of course, been mainly in the department of Organic Chemistry, which has made such rapid progress within the last few years, but yet equal attention has been bestowed on the other branches of the subject—Chemical Physics and Inorganic Chemistry—to present all investigations and discoveries of importance, and to keep up the reputation of the volume as a complete manual of the whole science, admirably adapted for the learner. By the use of a small but exceedingly clear type the matter of a large octavo is compressed within the convenient and portable limits of a moderate sized duodecimo, and at the very low price affixed, it is offered as one of the cheapest volumes before the profession.

Dr. Fownes' excellent work has been universally recognized everywhere in his own and this country, as the best elementary treatise on chemistry in the English tongue, and is very generally adopted, we believe, as the standard text-book in all our colleges, both literary and scientific.—*Charleston Med. Journ. and Review.*

A standard manual, which has long enjoyed the reputation of embodying much knowledge in a small space. The author has achieved the difficult task of condensation with masterly tact. His book is concise without being dry, and brief without being too dogmatical or general.—*Virginia Med. and Surgical Journal.*

The work of Dr. Fownes has long been before the public, and its merits have been fully appreciated as the best text-book on chemistry now in existence. We do not, of course, place it in a rank superior to the works of Brande, Graham, Turner, Gregory, or Gmelin, but we say that, as a work for students, it is preferable to any of them.—*London Journal of Medicine.*

A work well adapted to the wants of the student. It is an excellent exposition of the chief doctrines and facts of modern chemistry. The size of the work, and still more the condensed yet perspicuous style in which it is written, absolve it from the charges very properly urged against most manuals termed popular.—*Edinburgh Journal of Medical Science.*

**FISKE FUND PRIZE ESSAYS.—THE EFFECTS OF CLIMATE ON TUBERCULOUS DISEASE.** By EDWIN LEE, M. R. C. S., London, and **THE INFLUENCE OF PREGNANCY ON THE DEVELOPMENT OF TUBERCLES** By

EDWARD WARREN, M. D., of Edenton, N. C. Together in one neat 8vo. volume, extra cloth, \$1 00. **FRICK ON RENAL AFFECTIONS;** their Diagnosis and Pathology. With illustrations. One volume, royal 12mo., extra cloth. 75 cents

FERGUSON (WILLIAM), F. R. S.,

Professor of Surgery in King's College, London, &amp;c.

**A SYSTEM OF PRACTICAL SURGERY.** Fourth American, from the third and enlarged London edition. In one large and beautifully printed octavo volume, of about 700 pages, with 393 handsome illustrations, leather. \$3 00.

GRAHAM (THOMAS), F. R. S.

**THE ELEMENTS OF INORGANIC CHEMISTRY,** including the Applications of the Science in the Arts. New and much enlarged edition, by HENRY WATTS and ROBERT BRIDGES, M. D. Complete in one large and handsome octavo volume, of over 800 very large pages, with two hundred and thirty-two wood-cuts, extra cloth. \$4 00.

\* \* \* Part II., completing the work from p. 431 to end, with Index, Title Matter, &c., may be had separate, cloth backs and paper sides. Price \$2 50.

From Prof. E. N. Horsford, Harvard College.

It has, in its earlier and less perfect editions, been familiar to me, and the excellence of its plan and the clearness and completeness of its discussions, have long been my admiration.

No reader of English works on this science can

afford to be without this edition of Prof. Graham's Elements.—*Silliman's Journal*, March, 1853.

From Prof. Wolcott Gibbs, N. Y. Free Academy.

The work is an admirable one in all respects, and its republication here cannot fail to exert a positive influence upon the progress of science in this country.

GRIFFITH (ROBERT E.), M. D., &amp;c.

**A UNIVERSAL FORMULARY,** containing the methods of Preparing and Administering Official and other Medicines. The whole adapted to Physicians and Pharmacutists. SECOND EDITION, thoroughly revised, with numerous additions, by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume, extra cloth, of 650 pages, double columns. \$3 00; or in sheep, \$3 25.

It was a work requiring much perseverance, and when published was looked upon as by far the best work of its kind that had issued from the American press. Prof. Thomas has certainly "improved," as well as added to this Formulary, and has rendered it additionally deserving of the confidence of pharmacutists and physicians.—*Am. Journal of Pharmacy.*

We are happy to announce a new and improved edition of this, one of the most valuable and useful works that have emanated from an American pen. It would do credit to any country, and will be found of daily usefulness to practitioners of medicine; it is better adapted to their purposes than the dispensatories.—*Southern Med. and Surg. Journal.*

It is one of the most useful books a country practitioner can possibly have.—*Medical Chronicle.*

This is a work of six hundred and fifty-one pages, embracing all on the subject of preparing and administering medicines that can be desired by the physician and pharmacist.—*Western Lancet.*

The amount of useful, every-day matter for a practicing physician, is really immense.—*Boston Med and Surg. Journal.*

This edition has been greatly improved by the revision and ample additions of Dr. Thomas, and is now, we believe, one of the most complete works of its kind in any language. The additions amount to about seventy pages, and no effort has been spared to include in them all the recent improvements. A work of this kind appears to us indispensable to the physician, and there is none we can more cordially recommend. *N Y Journal of Medicine.*

GROSS (SAMUEL D.), M. D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia, &amp;c.

Enlarged Edition—Now Ready, January, 1862.

**A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative.** Illustrated by TWELVE HUNDRED AND TWENTY-SEVEN ENGRAVINGS. Second edition, much enlarged and carefully revised. In two large and beautifully printed octavo volumes, of about twenty-two hundred pages; strongly bound in leather, with raised bands. Price \$12.

The exhaustion in little more than two years of a large edition of so elaborate and comprehensive a work as this is the best evidence that the author was not mistaken in his estimate of the want which existed of a complete American System of Surgery, presenting the science in all its necessary details and in all its branches. That he has succeeded in the attempt to supply this want is shown not only by the rapid sale of the work, but also by the very favorable manner in which it has been received by the organs of the profession in this country and in Europe, and by the fact that a translation is now preparing in Holland—a mark of appreciation not often bestowed on any scientific work so extended in size.

The author has not been insensible to the kindness thus bestowed upon his labors, and in revising the work for a new edition he has spared no pains to render it worthy of the favor with which it has been received. Every portion has been subjected to close examination and revision; any deficiencies apparent have been supplied, and the results of recent progress in the science and art of surgery have been everywhere introduced; while the series of illustrations has been enlarged by the addition of nearly three hundred wood-cuts, rendering it one of the most thoroughly illustrated works ever laid before the profession. To accommodate these very extensive additions, the work has been printed upon a smaller type, so that notwithstanding the very large increase in the matter and value of the book, its size is more convenient and less cumbersome than before. Every care has been taken in the printing to render the typographical execution unexceptionable, and it is confidently presented as a work in every way worthy of a place in even the most limited library of the practitioner or student.

A few testimonials of the value of the former edition are appended.

Has Dr. Gross satisfactorily fulfilled this object? A careful perusal of his volumes enables us to give an answer in the affirmative. Not only has he given to the reader an elaborate and well-written account of his own vast experience, but he has not failed to embody in his pages the opinions and practice of surgeons in this and other countries of Europe. The result has been a work of such completeness, that it has no superior in the systematic treatises on surgery which have emanated from English or Continental authors. It has been justly objected that these have been far from complete in many essential particulars, many of them having been deficient in some of the most important points which should characterize such works. Some of them have been elaborate—too elaborate—with respect to certain diseases, while they have merely glanced at, or given an unsatisfactory account of, others equally important to the surgeon. Dr. Gross has avoided his error, and has produced the most complete work that has yet issued from the press on the science and practice of surgery. It is not, strictly speaking, a Dictionary of Surgery, but it gives to the reader all the information that he may require for his treatment of surgical diseases. Having said so much, it might appear superfluous to add another word; but it is only due to Dr. Gross to state that he has embraced the opportunity of transferring to his pages a vast number of engravings from English and other authors, illustrative of the pathology and treatment of surgical diseases. To these are added several hundred original wood-cuts. The work altogether commends itself to the attention of British surgeons, from whom it cannot fail to meet with extensive patronage.—*London Lancet*, Sept. 1, 1860.

Of Dr. Gross's treatise on Surgery we can say no more than that it is the most elaborate and complete work on this branch of the healing art which has ever been published in any country. A systematic work, it admits of no analytical review; but, did our space permit, we should gladly give some extracts from it, to enable our readers to judge of the classical style of the author, and the exhausting way in which each subject is treated.—*Dublin Quarterly Journal of Med. Science*.

The work is so superior to its predecessors in matter and extent, as well as in illustrations and style of publication, that we can honestly recommend it as the best work of the kind to be taken home by the young practitioner.—*Am. Med. Journ.*

With pleasure we record the completion of this long-anticipated work. The reputation which the author has for many years sustained, both as a surgeon and as a writer, had prepared us to expect a treatise of great excellence and originality; but we confess we were by no means prepared for the work which is before us—the most complete treatise upon surgery ever published, either in this or any other country, and we might, perhaps, safely say, the most original. There is no subject belonging properly to surgery which has not received from the author a due share of attention. Dr. Gross has supplied a want in surgical literature which has long been felt by practitioners; he has furnished us with a complete practical treatise upon surgery in all its departments. As Americans, we are proud of the achievement; as surgeons, we are most sincerely thankful to him for his extraordinary labors on our behalf.—*N. Y. Monthly Review and Buffalo Med. Journal*.

BY THE SAME AUTHOR.

**ELEMENTS OF PATHOLOGICAL ANATOMY.** Third edition, thoroughly revised and greatly improved. In one large and very handsome octavo volume, with about three hundred and fifty beautiful illustrations, of which a large number are from original drawings. Price in extra cloth, \$4 75; leather, raised bands, \$5 25. (*Lately Published.*)

The very rapid advances in the Science of Pathological Anatomy during the last few years have rendered essential a thorough modification of this work, with a view of making it a correct exponent of the present state of the subject. The very careful manner in which this task has been executed, and the amount of alteration which it has undergone, have enabled the author to say that "with the many changes and improvements now introduced, the work may be regarded almost as a new treatise," while the efforts of the author have been seconded as regards the mechanical execution of the volume, rendering it one of the handsomest productions of the American press.

We most sincerely congratulate the author on the successful manner in which he has accomplished his proposed object. His book is most admirably calculated to fill up a blank which has long been felt to exist in this department of medical literature, and as such must become very widely circulated amongst all classes of the profession.—*Dublin Quarterly Journ. of Med. Science*, Nov. 1857.

We have been favorably impressed with the general manner in which Dr. Gross has executed his task of affording a comprehensive digest of the present state of the literature of Pathological Anatomy, and have much pleasure in recommending his work to our readers, as we believe one well deserving of diligent perusal and careful study.—*Montreal Med. Chron.*, Sept. 1857.

BY THE SAME AUTHOR.

**A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES.** In one handsome octavo volume, extra cloth, with illustrations. pp. 468. \$2 75.

## GROSS (SAMUEL D.), M. D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia, &amp;c.

**A PRACTICAL TREATISE ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE URINARY BLADDER, THE PROSTATE GLAND, AND THE URETHRA.** Second Edition, revised and much enlarged, with one hundred and eighty-four illustrations. In one large and very handsome octavo volume, of over nine hundred pages. In leather, raised bands, \$5 25; extra cloth, \$4 75.

Philosophical in its design, methodical in its arrangement, ample and sound in its practical details, it may in truth be said to leave scarcely anything to be desired on so important a subject.—*Boston Med. and Surg. Journal*.

Whoever will peruse the vast amount of valuable practical information it contains, will, we think,

agree with us, that there is no work in the English language which can make any just pretensions to be its equal.—*N. Y. Journal of Medicine*.

A volume replete with truths and principles of the utmost value in the investigation of these diseases.—*American Medical Journal*.

## GRAY (HENRY), F. R. S.,

Lecturer on Anatomy at St. George's Hospital, London, &amp;c.

**ANATOMY, DESCRIPTIVE AND SURGICAL.** The Drawings by H. V.

CARTER, M. D., late Demonstrator on Anatomy at St. George's Hospital; the Dissections jointly by the AUTHOR and Dr. CARTER. Second American, from the second revised and improved London edition. In one magnificent imperial octavo volume, of over 800 pages, with 388 large and elaborate engravings on wood. Price in extra cloth, \$6 25; leather, raised bands, \$7 00. (*Now Ready*, 1862.)

The speedy exhaustion of a large edition of this work is sufficient evidence that its plan and execution have been found to present superior practical advantages in facilitating the study of Anatomy. In presenting it to the profession a second time, the author has availed himself of the opportunity to supply any deficiencies which experience in its use had shown to exist, and to correct any errors of detail, to which the first edition of a scientific work on so extensive and complicated a science is liable. These improvements have resulted in some increase in the size of the volume, while twenty-six new wood-cuts have been added to the beautiful series of illustrations which form so distinctive a feature of the work. The American edition has been passed through the press under the supervision of a competent professional man, who has taken every care to render it in all respects accurate, and it is now presented, without any increase of price, as fitted to maintain and extend the popularity which it has everywhere acquired.

With little trouble, the busy practitioner whose knowledge of anatomy may have become obscured by want of practice, may now resuscitate his former anatomical lore, and be ready for any emergency. It is to this class of individuals, and not to the student alone, that this work will ultimately tend to be of most incalculable advantage, and we feel satisfied that the library of the medical man will soon be considered incomplete in which a copy of this work does not exist.—*Madras Quarterly Journal of Med. Science*, July, 1861.

This edition is much improved and enlarged, and contains several new illustrations by Dr. Westmacott. The volume is a complete companion to the dissecting-room, and saves the necessity of the student possessing a variety of "Manuals."—*The London Lancet*, Feb. 9, 1861.

The work before us is one entitled to the highest praise, and we accordingly welcome it as a valuable addition to medical literature. Intermediate in fulness of detail between the treatises of Snarpey and of Wilson, its characteristic merit lies in the number and excellence of the engravings it contains. Most of these are original, of much larger than ordinary size, and admirably executed. The various parts are also lettered after the plan adopted in Holden's Osteology. It would be difficult to over-estimate the advantages offered by this mode of pictorial illustration. Bones, ligaments, muscles, bloodvessels, and nerves are each in turn figured, and marked with their appropriate names; thus enabling the student to comprehend, at a glance, what would otherwise often be ignored, or at any rate, acquired only by prolonged and irksome application. In conclusion, we heartily commend the work of Mr. Gray to the attention of the medical profession, feeling certain that it should be regarded as one of the most valuable contributions ever made to educational literature.—*N. Y. Monthly Review*. Dec. 1859.

In this view, we regard the work of Mr. Gray as far better adapted to the wants of the profession, and especially of the student, than any treatise on anatomy yet published in this country. It is destined, we believe, to supersede all others, both as a manual of dissections, and a standard of reference to the student of general or relative anatomy.—*N. Y. Journal of Medicine*, Nov. 1859.

For this truly admirable work the profession is indebted to the distinguished author of "Gray on the Spleen." The vacancy it fills has been long felt

to exist in this country. Mr. Gray writes throughout with both branches of his subject in view. His description of each particular part is followed by a notice of its relations to the parts with which it is connected, and this, too, sufficiently ample for all the purposes of the operative surgeon. After describing the bones and muscles, he gives a concise statement of the fractures to which the bones of the extremities are most liable, together with the amount and direction of the displacement to which the fragments are subjected by muscular action. The section on arteries is remarkably full and accurate. Not only is the surgical anatomy given to every important vessel, with directions for its ligation, but at the end of the description of each arterial trunk we have a useful summary of the irregularities which may occur in its origin, course, and termination.—*N. A. Med. Chir. Review*, Mar. 1859.

Mr. Gray's book, in excellency of arrangement and completeness of execution, exceeds any work on anatomy hitherto published in the English language, affording a complete view of the structure of the human body, with especial reference to practical surgery. Thus the volume constitutes a perfect book of reference for the practitioner, demanding a place in even the most limited library of the physician or surgeon, and a work of necessity for the student to fix in his mind what he has learned by the dissecting knife from the book of nature.—*The Dublin Quarterly Journal of Med. Sciences*, Nov. 1858.

In our judgment, the mode of illustration adopted in the present volume cannot but present many advantages to the student of anatomy. To the zealous disciple of Vesalius, earnestly desirous of real improvement, the book will certainly be of immense value; but, at the same time, we must also confess that to those simply desirous of "cramming" it will be an undoubted godsend. The peculiar value of Mr. Gray's mode of illustration is nowhere more markedly evident than in the chapter on osteology, and especially in those portions which treat of the bones of the head and of their development. The study of these parts is thus made one of comparative ease, if not of positive pleasure; and those bugbears of the student, the temporal and sphenoid bones, are shorn of half their terrors. It is, in our estimation, an admirable and complete text-book for the student, and a useful work of reference for the practitioner; its pictorial character forming a novel element, to which we have already sufficiently alluded.—*Am. Journ. Med. Sci.*, July, 1859.

**GIBSON'S INSTITUTES AND PRACTICE OF SURGERY.** Eighth edition, improved and altered. With thirty-four plates. In two handsome octavo volumes, containing about 1,000 pages, leather, raised band. \$6 50.

**GARDNER'S MEDICAL CHEMISTRY,** for the use of Students and the Profession. In one royal 12mo. vol., cloth, pp. 396, with wood-cuts. \$1.

**GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY.** Translated, with Notes and Addi-

tions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, extra cloth, with 320 copper-plate figures, plain and colored, \$5 00.

**HUGHES' INTRODUCTION TO THE PRACTICE OF AUSCULTATION AND OTHER MODES OF PHYSICAL DIAGNOSIS, IN DISEASES OF THE LUNGS AND HEART.** Second edition 1 vol. royal 12mo., ex. cloth, pp. 304. \$1 00.

**HAMILTON (FRANK H.), M. D.,**  
Professor of Surgery in the Long Island College Hospital.

**A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS.** In one large and handsome octavo volume, of over 750 pages, with 289 illustrations. \$4 25. (*Now Ready*, January, 1860.)

Among the many good workers at surgery of whom America may now boast not the least is Frank Hamilton; and the volume before us is (we say it with a pang of wounded patriotism) the best and handiest book on the subject in the English language. It is in vain to attempt a review of it; nearly as vain to seek for any sins, either of commission or omission. We have seen no work on practical surgery which we would sooner recommend to our brother surgeons, especially those of "the services," or those whose practice lies in districts where a man has necessarily to rely on his own unaided resources. The practitioner will find in it directions for nearly every possible accident, easily found and comprehended; and much pleasant reading for him to muse over in the after consideration of his cases.—*Edinburgh Med. Journ.* Feb. 1861.

This is a valuable contribution to the surgery of most important affections, and is the more welcome, inasmuch as at the present time we do not possess a single complete treatise on Fractures and Dislocations in the English language. It has remained for our American brother to produce a complete treatise upon the subject, and bring together in a convenient form those alterations and improvements that have been made from time to time in the treatment of these affections. One great and valuable feature in the work before us is the fact that it comprises all the improvements introduced into the practice of both English and American surgery, and though far from omitting mention of our continental neighbors, the author by no means encourages the notion—but too prevalent in some quarters—that nothing is good unless imported from France or Germany. The latter half of the work is devoted to the consideration of the various dislocations and their appropriate treatment, and its merit is fully equal to that of the preceding portion.—*The London Lancet*, May 5, 1860.

It is emphatically *the* book upon the subjects of which it treats, and we cannot doubt that it will continue so to be for an indefinite period of time. When we say, however, that we believe it will at once take its place as the best book for consultation by the practitioner; and that it will form the most complete, available, and reliable guide in emergencies of every nature connected with its subjects; and also that the student of surgery may make it his textbook with entire confidence, and with pleasure also, from its agreeable and easy style—we think our own

opinion may be gathered as to its value.—*Boston Medical and Surgical Journal*, March 1, 1860.

The work is concise, judicious, and accurate, and adapted to the wants of the student, practitioner, and investigator, honorable to the author and to the profession.—*Chicago Med. Journal*, March, 1860.

We regard this work as an honor not only to its author, but to the profession of our country. Were we to review it thoroughly, we could not convey to the mind of the reader more forcibly our honest opinion expressed in the few words—we think it the best book of its kind extant. Every man interested in surgery will soon have this work on his desk. He who does not, will be the loser.—*New Orleans Medical News*, March, 1860.

Now that it is before us, we feel bound to say that much as was expected from it, and onerous as was the undertaking, it has surpassed expectation, and achieved more than was pledged in its behalf; for its title does not express in full the richness of its contents. On the whole, we are prouder of this work than of any which has for years emanated from the American medical press; its sale will certainly be very large in this country, and we anticipate its eliciting much attention in Europe.—*Nashville Medical Record*, Mar. 1860.

Every surgeon, young and old, should possess himself of it, and give it a careful perusal, in doing which he will be richly repaid.—*St. Louis Med. and Surg. Journal*, March, 1860.

Dr. Hamilton is fortunate in having succeeded in filling the void, so long felt, with what cannot fail to be at once accepted as a model monograph in some respects, and a work of classical authority. We sincerely congratulate the profession of the United States on the appearance of such a publication from one of their number. We have reason to be proud of it as an original work, both in a literary and scientific point of view, and to esteem it as a valuable guide in a most difficult and important branch of study and practice. On every account, therefore, we hope that it may soon be widely known abroad as an evidence of genuine progress on this side of the Atlantic, and further, that it may be still more widely known at home as an authoritative teacher from which every one may profitably learn, and as affording an example of honest, well-directed, and untiring industry in authorship which every surgeon may emulate.—*Am. Med. Journal*, April, 1860.

**HOBLYN (RICHARD D.), M. D.**

**A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES.** A new American edition. Revised, with numerous Additions, by ISAAC HAYS, M. D., editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume, leather, of over 500 double columned pages. \$1 50.

To both practitioner and student, we recommend this dictionary as being convenient in size, accurate in definition, and sufficiently full and complete for ordinary consultation.—*Charleston Med. Journ.*

We know of no dictionary better arranged and adapted. It is not encumbered with the obsolete terms of a bygone age, but it contains all that are now in

use; embracing every department of medical science down to the very latest date.—*Western Lancet*.

Hoblyn's Dictionary has long been a favorite with us. It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg. Journal*.

**HOLLAND'S MEDICAL NOTES AND REFLECTIONS.** From the third London edition.

In one handsome octavo volume, extra cloth. \$3.

**HORNER'S SPECIAL ANATOMY AND HIS-**

**TOLOGY.** Eighth edition. Extensively revised and modified. In two large octavo volumes, extra cloth, of more than 1000 pages, with over 300 illustrations. \$6 00.

HODGE (HUGH L.), M. D.,

Professor of Midwifery and the Diseases of Women and Children in the University of Pennsylvania, &amp;c.

**ON DISEASES PECULIAR TO WOMEN**, including Displacements of the Uterus. With original illustrations. In one beautifully printed octavo volume, of nearly 500 pages, extra cloth. \$3 25. (*Now Ready.*)

We will say at once that the work fulfils its object capitally well; and we will moreover venture the assertion that it will inaugurate an improved practice throughout this whole country. The secrets of the author's success are so clearly revealed that the attentive student cannot fail to insure a goodly portion of similar success in his own practice. It is a credit to *all* medical literature; and we add, that the physician who does not place it in his library, and who does not faithfully con its pages, will lose a vast deal of knowledge that would be most useful to himself and beneficial to his patients. *It is a practical work of the highest order of merit; and it will take rank as such immediately.*—*Maryland and Virginia Medical Journal*, Feb. 1861.

This contribution towards the elucidation of the pathology and treatment of some of the diseases peculiar to women, cannot fail to meet with a favorable reception from the medical profession. The character of the particular maladies of which the work before us treats; their frequency, variety, and obscurity; the amount of malaise and even of actual suffering by which they are invariably attended; their obstinacy, the difficulty with which they are overcome, and their disposition again and again to recur—these, taken in connection with the entire competency of the author to render a correct account of their nature, their causes, and their appro-

priate management—his ample experience, his matured judgment, and his perfect conscientiousness—invest this publication with an interest and value to which few of the medical treatises of a recent date can lay a stronger, if, perchance, an equal claim.—*Am. Journ. Med. Sciences*, Jan. 1861.

Indeed, although no part of the volume is not eminently deserving of perusal and study, we think that the nine chapters devoted to this subject, are especially so, and we know of no more valuable monograph upon the symptoms, prognosis, and management of these annoying maladies than is constituted by this part of the work. We cannot but regard it as one of the most original and most practical works of the day; one which every accoucheur and physician should most carefully read; for we are persuaded that he will arise from its perusal with new ideas, which will induct him into a more rational practice in regard to many a suffering female, who may have placed her health in his hands.—*British American Journal*, Feb. 1861.

Of the many excellences of the work we will not speak at length. We advise all who would acquire a knowledge of the proper management of the maladies of which it treats, to study it with care. The second part is of itself a most valuable contribution to the practice of our art.—*Am. Med. Monthly and New York Review*, Feb. 1861.

The illustrations, which are all original, are drawn to a uniform scale of one-half the natural size.

HABERSHON (S. O.), M. D.,

Assistant Physician to and Lecturer on Materia Medica and Therapeutics at Guy's Hospital, &amp;c.

**PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON DISEASES OF THE ALIMENTARY CANAL, ŒSOPHAGUS, STOMACH, CÆCUM, AND INTES-TINES.** With illustrations on wood. In one handsome octavo volume of 312 pages, extra cloth \$1 75. (*Now Ready.*)

JONES (T. WHARTON), F. R. S.,

Professor of Ophthalmic Medicine and Surgery in University College, London, &amp;c.

**THE PRINCIPLES AND PRACTICE OF OPHTHALMIC MEDICINE AND SURGERY.** With one hundred and ten illustrations. Second American from the second and revised London edition, with additions by EDWARD HARTSHORNE, M. D., Surgeon to Wills' Hospital, &c. In one large, handsome royal 12mo. volume, extra cloth, of 500 pages. \$1 50.

**JONES (C. HANDFIELD), F. R. S., & EDWARD H. SIEVEKING, M. D.,**  
Assistant Physicians and Lecturers in St. Mary's Hospital, London.

**A MANUAL OF PATHOLOGICAL ANATOMY.** First American Edition, Revised. With three hundred and ninety-seven handsome wood engravings. In one large and beautiful octavo volume of nearly 750 pages, leather. \$3 75.

As a concise text-book, containing, in a condensed form, a complete outline of what is known in the domain of Pathological Anatomy, it is perhaps the best work in the English language. Its great merit consists in its completeness and brevity, and in this respect it supplies a great desideratum in our literature. Heretofore the student of pathology was

obliged to glean from a great number of monographs, and the field was so extensive that but few cultivated it with any degree of success. As a simple work of reference, therefore, it is of great value to the student of pathological anatomy, and should be in every physician's library.—*Western Lancet*.

KIRKES (WILLIAM SENHOUSE), M. D.,

Demonstrator of Morbid Anatomy at St. Bartholomew's Hospital, &amp;c.

**A MANUAL OF PHYSIOLOGY.** A new American, from the third and improved London edition. With two hundred illustrations. In one large and handsome royal 12mo. volume, leather. pp. 586. \$2 00. (*Lately Published.*)

This is a new and very much improved edition of Dr. Kirk's well-known Handbook of Physiology. It combines conciseness with completeness, and is, therefore, admirably adapted for consultation by the busy practitioner.—*Dublin Quarterly Journal*.

One of the very best handbooks of Physiology we possess—presenting just such an outline of the science as the student requires during his attendance upon a course of lectures, or for reference whilst preparing for examination.—*Am. Medical Journal*

Its excellence is in its compactness, its clearness,

and its carefully cited authorities. It is the most convenient of text-books. These gentlemen, Messrs. Kirkes and Paget, have the gift of telling us what we want to know, without thinking it necessary to tell us all they know.—*Boston Med and Surg. Journal*.

For the student beginning this study, and the practitioner who has but leisure to refresh his memory, this book is invaluable, as it contains all that it is important to know.—*Charleston Med. Journal*.

**KNAPP'S TECHNOLOGY**; or, Chemistry applied to the Arts and to Manufactures. Edited by Dr. RONALDS, Dr. RICHARDSON, and Prof. W. R. JOHNSON. In two handsome 8vo. vols., without 500 wood engravings. \$6 00.

**LAYCOCK'S LECTURES ON THE PRINCIPLES AND METHODS OF MEDICAL OBSERVATION AND RESEARCH.** For the Use of Advanced Students and Junior Practitioners. In one royal 12mo. volume, extra cloth. Price \$1.

### LALLEMAND AND WILSON.

**A PRACTICAL TREATISE ON THE CAUSES, SYMPTOMS, AND TREATMENT OF SPERMATORRHEA.** By M. LALLEMAND. Translated and edited by HENRY J. McDOUGALL. Third American edition. To which is added — **ON DISEASES OF THE VESICULÆ SEMINALES; AND THEIR ASSOCIATED ORGANS.** With special reference to the Morbid Secretions of the Prostatic and Urethral Mucous Membrane. By MARRIS WILSON, M. D. In one neat octavo volume, of about 400 pp., extra cloth. \$2 00. (*Just Issued.*)

### LA ROCHE (R.), M. D., &c.

**YELLOW FEVER**, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. Including a Sketch of the Disease as it has occurred in Philadelphia from 1699 to 1854, with an examination of the connections between it and the fevers known under the same name in other parts of temperate as well as in tropical regions. In two large and handsome octavo volumes of nearly 1500 pages, extra cloth. \$7 00.

From Professor S. H. Dickinson, Charleston, S. C., September 18, 1855.

A monument of intelligent and well applied research, almost without example. It is, indeed, in itself, a large library, and is destined to constitute the special resort as a book of reference, in the subject of which it treats, to all future time.

We have not time at present, engaged as we are, by day and by night, in the work of combating this very disease, now prevailing in our city, to do more than give this cursory notice of what we consider as undoubtedly the most able and erudite medical publication our country has yet produced. But in view of the startling fact, that this, the most malign

and unmanageable disease of modern times, has for several years been prevailing in our country to a greater extent than ever before; that it is no longer confined to either large or small cities, but penetrates country villages, plantations, and farm-houses; that it is treated with scarcely better success now than thirty or forty years ago; that there is vast mischief done by ignorant pretenders to knowledge in regard to the disease, and in view of the probability that a majority of southern physicians will be called upon to treat the disease, we trust that this able and comprehensive treatise will be very generally read in the south.—*Memphis Med. Recorder.*

BY THE SAME AUTHOR.

**PNEUMONIA**; its Supposed Connection, Pathological and Etiological, with Autumnal Fevers, including an Inquiry into the Existence and Morbid Agency of Malaria. In one handsome octavo volume, extra cloth, of 500 pages. \$3 00.

### LAWRENCE (W.), F. R. S., &c.

**A TREATISE ON DISEASES OF THE EYE.** A new edition, edited, with numerous additions, and 243 illustrations, by ISAAC HAYS, M. D., Surgeon to Will's Hospital, &c. In one very large and handsome octavo volume, of 950 pages, strongly bound in leather with raised bands. \$5 00.

### LUDLOW (J. L.), M. D.

**A MANUAL OF EXAMINATIONS** upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume, leather, of 816 large pages. \$2 50.

We know of no better companion for the student during the hours spent in the lecture room, or to refresh, at a glance, his memory of the various topics

crammed into his head by the various professors to whom he is compelled to listen.—*Western Lancet*, May, 1857.

### LEHMANN (C. G.)

**PHYSIOLOGICAL CHEMISTRY.** Translated from the second edition by GEORGE E. DAY, M. D., F. R. S., &c., edited by R. E. ROGERS, M. D., Professor of Chemistry in the Medical Department of the University of Pennsylvania, with illustrations selected from Funke's Atlas of Physiological Chemistry, and an Appendix of plates. Complete in two large and handsome octavo volumes, extra cloth, containing 1200 pages, with nearly two hundred illustrations. \$6 00.

The work of Lehmann stands unrivalled as the most comprehensive book of reference and information extant on every branch of the subject on which it treats.—*Edinburgh Journal of Medical Science.*

The most important contribution as yet made to Physiological Chemistry.—*Am. Journal Med. Sciences*, Jan. 1856.

BY THE SAME AUTHOR. (*Lately Published.*)

**MANUAL OF CHEMICAL PHYSIOLOGY.** Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M. D., with an Introductory Essay on Vital Force, by Professor SAMUEL JACKSON, M. D., of the University of Pennsylvania. With illustrations on wood. In one very handsome octavo volume, extra cloth, of 336 pages. \$2 25.

From Prof. Jackson's *Introductory Essay.*

In adopting the handbook of Dr. Lehmann as a manual of Organic Chemistry for the use of the students of the University, and in recommending his original work of **PHYSIOLOGICAL CHEMISTRY** for their more mature studies, the high value of his researches, and the great weight of his authority in that important department of medical science are fully recognized.

LYONS (ROBERT D.), K. C. C.,

Late Pathologist in-chief to the British Army in the Crimea, &amp;c.

**A TREATISE ON FEVER;** or, selections from a course of Lectures on Fever. Being part of a course of Theory and Practice of Medicine. In one neat octavo volume, of 362 pages, extra cloth; \$2 00. (*Now Ready.*)

*From the Author's Preface.*

"I am induced to publish this work on Fever with a view to bring within the reach of the student and junior practitioner, in a convenient form, the more recent results of inquiries into the Pathology and Therapeutics of this formidable class of diseases.

"The works of the great writers on Fever are so numerous, and in the present day are scattered in so many languages, that they are difficult of access, not only to students but also to practitioners. I shall deem myself fortunate if I can in any measure supply the want which is felt in this respect.

We have great pleasure in recommending Dr. Lyons' work on *Fever* to the attention of the profession. It is a work which cannot fail to enhance the author's previous well-earned reputation, as a diligent, careful, and accurate observer.—*British Med. Journal*, March 2, 1861.

Taken as a whole we can recommend it in the highest terms as well worthy the careful perusal and study of every student and practitioner of medi-

cine. We consider the work a most valuable addition to medical literature, and one destined to wield no little influence over the mind of the profession.—*Med and Surg. Reporter*, May 4, 1861.

This is an admirable work upon the most remarkable and most important class of diseases to which mankind are liable.—*Med. Journ. of N. Carolina*, May, 1861.

MEIGS (CHARLES D.), M. D.,

Professor of Obstetrics, &amp;c. in the Jefferson Medical College, Philadelphia.

**OBSTETRICS: THE SCIENCE AND THE ART.** Third edition, revised and improved. With one hundred and twenty-nine illustrations. In one beautifully printed octavo volume, leather, of seven hundred and fifty-two large pages. \$3 75.

Though the work has received only five pages of enlargement, its chapters throughout wear the impress of careful revision. Expunging and rewriting, remodelling its sentences, with occasional new material, all evince a lively desire that it shall deserve to be regarded as improved in manner as well as matter. In the matter, every stroke of the pen has increased the value of the book, both in expungings and additions.—*Western Lancet*, Jan. 1857.

The best American work on Midwifery that is accessible to the student and practitioner.—*N. W. Med. and Surg. Journal*, Jan. 1857.

This is a standard work by a great American Obstetrician. It is the third and last edition, and in the language of the preface, the author has "brought the subject up to the latest dates of real improvement in our art and Science."—*Nashville Journ. of Med. and Surg.*, May, 1857.

BY THE SAME AUTHOR. (*Just Issued.*)

**WOMAN: HER DISEASES AND THEIR REMEDIES.** A Series of Lectures to his Class. Fourth and Improved edition. In one large and beautifully printed octavo volume, leather, of over 700 pages. \$3 60.

In other respects, in our estimation, too much cannot be said in praise of this work. It abounds with beautiful passages, and for conciseness, for originality, and for all that is commendable in a work on the diseases of females, it is not excelled, and probably not equalled in the English language. On the whole, we know of no work on the diseases of women which we can so cordially commend to the student and practitioner as the one before us.—*Ohio Med. and Surg. Journal*.

The body of the book is worthy of attentive consideration, and is evidently the production of a clever, thoughtful, and sagacious physician. Dr. Meigs's letters on the diseases of the external organs, contain many interesting and rare cases, and many instructive observations. We take our leave of Dr. Meigs, with a high opinion of his talents and originality.—*The British and Foreign Medico-Chirurgical Review*.

Every chapter is replete with practical instruction, and bears the impress of being the composition of an acute and experienced mind. There is a terseness, and at the same time an accuracy in his description of symptoms, and in the rules for diagnosis,

which cannot fail to recommend the volume to the attention of the reader.—*Ranking's Abstract*.

It contains a vast amount of practical knowledge, by one who has accurately observed and retained the experience of many years.—*Dublin Quarterly Journal*.

Full of important matter, conveyed in a ready and agreeable manner.—*St. Louis Med. and Surg. Jour.*

There is an off-hand fervor, a glow, and a warm-heartedness infecting the effort of Dr. Meigs, which is entirely captivating, and which absolutely hurries the reader through from beginning to end. Besides, the book teems with solid instruction, and it shows the very highest evidence of ability, viz., the clearness with which the information is presented. We know of no better test of one's understanding a subject than the evidence of the power of lucidly explaining it. The most elementary, as well as the obscure subjects, under the pencil of Prof. Meigs, are isolated and made to stand out in such bold relief, as to produce distinct impressions upon the mind and memory of the reader.—*The Charleston Med. Journal*.

BY THE SAME AUTHOR.

**ON THE NATURE, SIGNS, AND TREATMENT OF CHILD BED FEVER.** In a Series of Letters addressed to the Students of his Class. In one handsome octavo volume, extra cloth, of 365 pages. \$2 50.

The instructive and interesting author of this work, whose previous labors have placed his countrymen under deep and abiding obligations, again challenges their admiration in the fresh and vigorous, attractive and racy pages before us. It is a de-

lectable book. \* \* \* This treatise upon child-bed fevers will have an extensive sale, being destined, as it deserves, to find a place in the library of every practitioner who scorns to lag in the rear.—*Nashville Journal of Medicine and Surgery*.

BY THE SAME AUTHOR; WITH COLORED PLATES.

**A TREATISE ON ACUTE AND CHRONIC DISEASES OF THE NECK OF THE UTERUS.** With numerous plates, drawn and colored from nature in the highest style of art. In one handsome octavo volume, extra cloth. \$4 50.

## MACLISE (JOSEPH), SURGEON.

**SURGICAL ANATOMY.** Forming one volume, very large imperial quarto.

With sixty-eight large and splendid Plates, drawn in the best style and beautifully colored. Containing one hundred and ninety Figures, many of them the size of life. Together with copious and explanatory letter-press. Strongly and handsomely bound in extra cloth, being one of the cheapest and best executed Surgical works as yet issued in this country. \$11 00.

\* \* The size of this work prevents its transmission through the post-office as a whole, but those who desire to have copies forwarded by mail, can receive them in five parts, done up in stout wrappers. Price \$9 00.

One of the greatest artistic triumphs of the age in Surgical Anatomy.—*British American Medical Journal*.

No practitioner whose means will admit should fail to possess it.—*Ranking's Abstract*.

Too much cannot be said in its praise; indeed, we have no language to do it justice.—*Ohio Medical and Surgical Journal*.

The most accurately engraved and beautifully colored plates we have ever seen in an American book—one of the best and cheapest surgical works ever published.—*Buffalo Medical Journal*.

It is very rare that so elegantly printed, so well illustrated, and so useful a work, is offered at so moderate a price.—*Charleston Medical Journal*.

Its plates can boast a superiority which places them almost beyond the reach of competition.—*Medical Examiner*.

Country practitioners will find these plates of immense value.—*N. Y. Medical Gazette*.

A work which has no parallel in point of accuracy and cheapness in the English language.—*N. Y. Journal of Medicine*.

We are extremely gratified to announce to the profession the completion of this truly magnificent work, which, as a whole, certainly stands unrivalled, both for accuracy of drawing, beauty of coloring, and all the requisite explanations of the subject in hand.—*The New Orleans Medical and Surgical Journal*.

This is by far the ablest work on Surgical Anatomy that has come under our observation. We know of no other work that would justify a student, in any degree, for neglect of actual dissection. In those sudden emergencies that so often arise, and which require the instantaneous command of minute anatomical knowledge, a work of this kind keeps the details of the dissecting-room perpetually fresh in the memory.—*The Western Journal of Medicine and Surgery*.

## MILLER (HENRY), M. D.,

Professor of Obstetrics and Diseases of Women and Children in the University of Louisville.

**PRINCIPLES AND PRACTICE OF OBSTETRICS, &c.; including the Treatment of Chronic Inflammation of the Cervix and Body of the Uterus considered as a frequent cause of Abortion.** With about one hundred illustrations on wood. In one very handsome octavo volume, of over 600 pages. (*Lately Published.*) \$3 75.

We congratulate the author that the task is done. We congratulate him that he has given to the medical public a work which will secure for him a high and permanent position among the standard authorities on the principles and practice of obstetrics. Congratulations are not less due to the medical profession of this country, on the acquisition of a treatise embodying the results of the studies, reflections, and experience of Prof. Miller. Few men, if any, in this country, are more competent than he to write on this department of medicine. Engaged for thirty-five years in an extended practice of obstetrics, for many years a teacher of this branch of instruction in one of the largest of our institutions, a diligent student as well as a careful observer, an original and independent thinker, wedded to no hobbies, ever ready to consider without prejudice new views, and to adopt innovations if they are really improvements, and withal a clear, agreeable writer, a practical treatise from his pen could not fail to possess great value.—*Buffalo Med Journal*.

In fact, this volume must take its place among the standard systematic treatises on obstetrics; a posi-

tion to which its merits justly entitle it. The style is such that the descriptions are clear, and each subject is discussed and elucidated with due regard to its practical bearings, which cannot fail to make it acceptable and valuable to both students and practitioners. We cannot, however, close this brief notice without congratulating the author and the profession on the production of such an excellent treatise. The author is a western man of whom we feel proud, and we cannot but think that his book will find many readers and warm admirers wherever obstetrics is taught and studied as a science and an art.—*The Cincinnati Lancet and Observer*.

A most respectable and valuable addition to our home medical literature, and one reflecting credit alike on the author and the institution to which he is attached. The student will find in this work a most useful guide to his studies; the country practitioner, rusty in his reading, can obtain from its pages a fair résumé of the modern literature of the science; and we hope to see this American production generally consulted by the profession.—*Va. Med. Journal*.

## MACKENZIE (W.), M. D.,

Surgeon Oculist in Scotland in ordinary to Her Majesty, &c. &c.

**A PRACTICAL TREATISE ON DISEASES AND INJURIES OF THE**

**EYE.** To which is prefixed an Anatomical Introduction explanatory of a Horizontal Section of the Human Eyeball, by THOMAS WHARTON JONES, F. R. S. From the Fourth Revised and Enlarged London Edition. With Notes and Additions by ADDINELL HEWSON, M. D., Surgeon to Wills Hospital, &c. &c. In one very large and handsome octavo volume, leather, raised bands, with plates and numerous wood-cuts. \$5 25.

The treatise of Dr. Mackenzie indisputably holds the first place, and forms, in respect of learning and research, an Encyclopædia unequalled in extent by any other work of the kind, either English or foreign.—*Dixon on Diseases of the Eye*.

Few modern books on any department of medicine or surgery have met with such extended circulation, or have procured for their authors a like amount of European celebrity. The immense research which it displayed, the thorough acquaintance with the subject, practically as well as theoretically, and the

able manner in which the author's stores of learning and experience were rendered available for general use, at once procured for the first edition, as well on the continent as in this country, that high position as a standard work which each successive edition has more firmly established. We consider it the duty of every one who has the love of his profession and the welfare of his patient at heart, to make himself familiar with this the most complete work in the English language upon the diseases of the eye.—*Med. Times and Gazette*.

**MAYNE'S DISPENSATORY AND THERAPEUTICAL REMEMBRANCER.** With every Practical Formula contained in the three British Pharmacopæias. Edited, with the addition of the Formulæ of the U. S. Pharmacopæia, by R. E. GRIFFITH, M. D. 12mo. vol. ex. cl., 300 pp. 75 c.

**MALGAIGNE'S OPERATIVE SURGERY,** based on Normal and Pathological Anatomy. Translated from the French by FREDERICK BRITAN, A. B., M. D. With numerous illustrations on wood. In one handsome octavo volume, extra cloth, of nearly six hundred pages. \$2 25.

MILLER (JAMES), F. R. S. E.,

Professor of Surgery in the University of Edinburgh, &amp;c.

**PRINCIPLES OF SURGERY.** Fourth American, from the third and revised Edinburgh edition. In one large and very beautiful volume, leather, of 700 pages, with two hundred and forty illustrations on wood. \$3 75.

The work of Mr. Miller is too well and too favorably known among us, as one of our best text-books, to render any further notice of it necessary than the announcement of a new edition, the fourth in our country, a proof of its extensive circulation among us. As a concise and reliable exposition of the science of modern surgery, it stands deservedly high—we know not its superior.—*Boston Med. and Surg. Journal.*

The work takes rank with Watson's Practice of Physic; it certainly does not fall behind that great work in soundness of principle or depth of reasoning and research. No physician who values his reputation, or seeks the interests of his clients, can acquit himself before his God and the world without making himself familiar with the sound and philosophical views developed in the foregoing book.—*New Orleans Med. and Surg. Journal.*

BY THE SAME AUTHOR. (*Just Issued.*)

**THE PRACTICE OF SURGERY.** Fourth American from the last Edinburgh edition. Revised by the American editor. Illustrated by three hundred and sixty-four engravings on wood. In one large octavo volume, leather, of nearly 700 pages. \$3 75.

No encomium of ours could add to the popularity of Miller's Surgery. Its reputation in this country is unsurpassed by that of any other work, and, when taken in connection with the author's *Principles of Surgery*, constitutes a whole, without reference to which no conscientious surgeon would be willing to practice his art.—*Southern Med. and Surg. Journal.*

It is seldom that two volumes have ever made so profound an impression in so short a time as the "Principles" and the "Practice" of Surgery by Mr. Miller—or so richly merited the reputation they have acquired. The author is an eminently sensible, practical, and well-informed man, who knows exactly what he is talking about and exactly how to talk it.—*Kentucky Medical Recorder.*

By the almost unanimous voice of the profession,

his works, both on the principles and practice of surgery have been assigned the highest rank. If we were limited to but one work on surgery, that one should be Miller's, as we regard it as superior to all others.—*St. Louis Med. and Surg. Journal.*

The author has in this and his "Principles," presented to the profession one of the most complete and reliable systems of Surgery extant. His style of writing is original, impressive, and engaging, energetic, concise, and lucid. Few have the faculty of condensing so much in small space, and at the same time so persistently holding the attention. Whether as a text-book for students or a book of reference for practitioners, it cannot be too strongly recommended.—*Southern Journal of Med. and Physical Sciences.*

MORLAND (W. W.), M. D.,

Fellow of the Massachusetts Medical Society, &amp;c.

**DISEASES OF THE URINARY ORGANS;** a Compendium of their Diagnosis, Pathology, and Treatment. With illustrations. In one large and handsome octavo volume, of about 600 pages, extra cloth. (*Just Issued.*) \$3 50.

Taken as a whole, we can recommend Dr. Morland's compendium as a very desirable addition to the library of every medical or surgical practitioner.—*Brit. and For. Med.-Chir. Rev.*, April, 1859.

Every medical practitioner whose attention has been to any extent attracted towards the class of diseases to which this treatise relates, must have often and sorely experienced the want of some full, yet concise recent compendium to which he could

refer. This desideratum has been supplied by Dr. Morland, and it has been ably done. He has placed before us a full, judicious, and reliable digest. Each subject is treated with sufficient minuteness, yet in a succinct, narrational style, such as to render the work one of great interest, and one which will prove in the highest degree useful to the general practitioner.—*N. Y. Journ. of Medicine.*

BY THE SAME AUTHOR.—(*Now Ready.*)

**THE MORBID EFFECTS OF THE RETENTION IN THE BLOOD OF THE ELEMENTS OF THE URINARY SECRETION.** Being the Dissertation to which the Fiske Fund Prize was awarded, July 11, 1861. In one small octavo volume, 83 pages, extra cloth. 75 cents.

MONTGOMERY (W. F.), M. D., M. R. I. A., &amp;c.,

Professor of Midwifery in the King and Queen's College of Physicians in Ireland, &amp;c.

**AN EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY.**

With some other Papers on Subjects connected with Midwifery. From the second and enlarged English edition. With two exquisite colored plates, and numerous wood-cuts. In one very handsome octavo volume, extra cloth, of nearly 600 pages. (*Lately Published.*) \$3 75.

A book unusually rich in practical suggestions.—*Am Journal Med. Sciences*, Jan. 1857.

These several subjects so interesting in themselves, and so important, every one of them, to the most delicate and precious of social relations, controlling often the honor and domestic peace of a family, the legitimacy of offspring, or the life of its parent, are all treated with an elegance of diction, fulness of illustrations, acuteness and justice of reasoning, unparalleled in obstetrics, and unsurpassed in medicine. The reader's interest can never flag, so

fresh, and vigorous, and classical is our author's style; and one forgets, in the renewed charm of every page, that it, and every line, and every word has been weighed and reweighed through years of preparation; that this is of all others the book of Obstetric Law, on each of its several topics; on all points connected with pregnancy, to be everywhere received as a manual of special jurisprudence, at once announcing fact, affording argument, establishing precedent, and governing alike the juryman, advocate, and judge.—*N. A. Med.-Chir. Review.*

MOHR (FRANCIS), PH. D., AND REDWOOD (THEOPHILUS).

**PRACTICAL PHARMACY.** Comprising the Arrangements, Apparatus, and Manipulations of the Pharmaceutical Shop and Laboratory. Edited, with extensive Additions, by Prof. WILLIAM PROCTER, of the Philadelphia College of Pharmacy. In one handsomely printed octavo volume, extra cloth, of 570 pages, with over 500 engravings on wood. \$2 75.

NEILL (JOHN), M. D.,

Surgeon to the Pennsylvania Hospital, &amp;c.; and

FRANCIS GURNEY SMITH, M. D.,

Professor of Institutes of Medicine in the Pennsylvania Medical College.

**AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES**

OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts. Strongly bound in leather, with raised bands. \$3 00.

The very flattering reception which has been accorded to this work, and the high estimate placed upon it by the profession, as evinced by the constant and increasing demand which has rapidly exhausted two large editions, have stimulated the authors to render the volume in its present revision more worthy of the success which has attended it. It has accordingly been thoroughly examined, and such errors as had on former occasions escaped observation have been corrected, and whatever additions were necessary to maintain it on a level with the advance of science have been introduced. The extended series of illustrations has been still further increased and much improved, while, by a slight enlargement of the page, these various additions have been incorporated without increasing the bulk of the volume.

The work is, therefore, again presented as eminently worthy of the favor with which it has hitherto been received. As a book for daily reference by the student requiring a guide to his more elaborate text-books, as a manual for preceptors desiring to stimulate their students by frequent and accurate examination, or as a source from which the practitioners of older date may easily and cheaply acquire a knowledge of the changes and improvement in professional science, its reputation is permanently established.

The best work of the kind with which we are acquainted.—*Med. Examiner.*

Having made free use of this volume in our examinations of pupils, we can speak from experience in recommending it as an admirable compend for students, and as especially useful to preceptors who examine their pupils. It will save the teacher much labor by enabling him readily to recall all of the points upon which his pupils should be examined. A work of this sort should be in the hands of every one who takes pupils into his office with a view of examining them; and this is unquestionably the best of its class.—*Transylvania Med. Journal*

In the rapid course of lectures, where work for

the students is heavy, and review necessary for an examination, a compend is not only valuable, but it is almost a *sine qua non*. The one before us is, in most of the divisions, the most unexceptionable of all books of the kind that we know of. The newest and soundest doctrines and the latest improvements and discoveries are explicitly, though concisely, laid before the student. There is a class to whom we very sincerely commend this cheap book as worth its weight in silver—that class is the graduates in medicine of more than ten years' standing, who have not studied medicine since. They will perhaps find out from it that the science is not exactly now what it was when they left it off.—*The Stethoscope.*

NELIGAN (J. MOORE), M. D., M. R. I. A., &amp;c.

**ATLAS OF CUTANEOUS DISEASES.** In one beautiful quarto volume, extra cloth, with splendid colored plates, presenting nearly one hundred elaborate representations of disease. \$4 50.

This beautiful volume is intended as a complete and accurate representation of all the varieties of Diseases of the Skin. While it can be consulted in conjunction with any work on Practice, it has especial reference to the author's "Treatise on Diseases of the Skin," so favorably received by the profession some years since. The publishers feel justified in saying that few more beautifully executed plates have ever been presented to the profession of this country.

Neligan's Atlas of Cutaneous Diseases supplies a long existing desideratum much felt by the largest class of our profession. It presents, in quarto size, 16 plates, each containing from 3 to 6 figures, and forming in all a total of 90 distinct representations of the different species of skin affections, grouped together in genera or families. The illustrations have been taken from nature, and have been copied with such fidelity that they present a striking picture of life; in which the reduced scale aptly serves to

give, at a *coup d'œil*, the remarkable peculiarities of each individual variety. And while thus the disease is rendered more definable, there is yet no loss of proportion incurred by the necessary concentration. Each figure is highly colored, and so truthful has the artist been that the most fastidious observer could not justly take exception to the correctness of the execution of the pictures under his scrutiny.—*Montreal Med. Chronicle.*

BY THE SAME AUTHOR.

**A PRACTICAL TREATISE ON DISEASES OF THE SKIN.** Third American edition. In one neat royal 12mo. volume, extra cloth, of 334 pages. \$1 00.

 The two volumes will be sent by mail on receipt of *Five Dollars*.

**OWEN ON THE DIFFERENT FORMS OF THE SKELETON, AND OF THE TEETH.**

One vol. royal 12mo., extra cloth with numerous illustrations. \$1 25

PIRRIE (WILLIAM), F. R. S. E.,

Professor of Surgery in the University of Aberdeen.

**THE PRINCIPLES AND PRACTICE OF SURGERY.** Edited by JOHN NEILL, M. D., Professor of Surgery in the Penna. Medical College, Surgeon to the Pennsylvania Hospital, &c. In one very handsome octavo volume, leather, of 780 pages, with 316 illustrations. \$3 75.

We know of no other surgical work of a reasonable size, wherein there is so much theory and practice, or where subjects are more soundly or clearly taught.—*The Stethoscope.*

Prof. Pirrie, in the work before us, has elaborately

discussed the principles of surgery, and a safe and effectual practice predicated upon them. Perhaps no work upon this subject heretofore issued is so full upon the science of the art of surgery.—*Nashville Journal of Medicine and Surgery.*

**PARRISH (EDWARD),**

Lecturer on Practical Pharmacy and Materia Medica in the Pennsylvania Academy of Medicine, &c.

**AN INTRODUCTION TO PRACTICAL PHARMACY.** Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmacist. With many Formulæ and Prescriptions. Second edition, greatly enlarged and improved. In one handsome octavo volume of 720 pages, with several hundred illustrations, extra cloth. \$3 50. (*Just Issued.*)

During the short time in which this work has been before the profession, it has been received with very great favor, and in assuming the position of a standard authority, it has filled a vacancy which had been severely felt. Stimulated by this encouragement, the author, in availing himself of the opportunity of revision, has spared no pains to render it more worthy of the confidence bestowed upon it, and his assiduous labors have made it rather a new book than a new edition, many portions having been rewritten, and much new and important matter added. These alterations and improvements have been rendered necessary by the rapid progress made by pharmaceutical science during the last few years, and by the additional experience obtained in the practical use of the volume as a text-book and work of reference. To accommodate these improvements, the size of the page has been materially enlarged, and the number of pages considerably increased, presenting in all nearly *one-half more* matter than the last edition. The work is therefore now presented as a complete exponent of the subject in its most advanced condition. From the most ordinary matters in the dispensing office, to the most complicated details of the vegetable alkaloids, it is hoped that everything requisite to the practising physician, and to the apothecary, will be found fully and clearly set forth, and that the new matter alone will be worth more than the very moderate cost of the work to those who have been consulting the previous edition.

That Edward Parrish, in writing a book upon practical Pharmacy some few years ago—one eminently original and unique—did the medical and pharmaceutical professions a great and valuable service, no one, we think, who has had access to its pages will deny; doubly welcome, then, is this new edition, containing the added results of his recent and rich experience as an observer, teacher, and practical operator in the pharmaceutical laboratory. The excellent plan of the first is more thoroughly, and in detail, carried out in this edition.—*Peninsular Med. Journal*, Jan. 1860.

Of course, all apothecaries who have not already a copy of the first edition will procure one of this; it is, therefore, to physicians residing in the country and in small towns, who cannot avail themselves of the skill of an educated pharmacist, that we would especially commend this work. In it they

will find all that they desire to know, and should know, but very little of which they do really know in reference to this important collateral branch of their profession; for it is a well established fact, that, in the education of physicians, while the science of medicine is generally well taught, very little attention is paid to the art of preparing them for use, and we know not how this defect can be so well remedied as by procuring and consulting Dr. Parrish's excellent work.—*St. Louis Med. Journal*, Jan. 1860.

We know of no work on the subject which would be more indispensable to the physician or student desiring information on the subject of which it treats. With Griffith's "Medical Formulary" and this, the practising physician would be supplied with nearly or quite all the most useful information on the subject.—*Charleston Med. Jour. and Review*, Jan. 1860

**PEASLEE (E. R.), M. D.,**

Professor of Physiology and General Pathology in the New York Medical College.

**HUMAN HISTOLOGY**, in its relations to Anatomy, Physiology, and Pathology; for the use of Medical Students. With four hundred and thirty-four illustrations. In one handsome octavo volume, of over 600 pages. (*Lately Published.*) \$3 75.

It embraces a library upon the topics discussed within itself, and is just what the teacher and learner need. Another advantage, by no means to be overlooked, everything of real value in the wide range which it embraces, is with great skill compressed into an octavo volume of but little more than six hundred pages. We have not only the whole subject of Histology, interesting in itself, ably and fully discussed, but what is of infinitely greater interest to the student, because of greater practical value, are its relations to Anatomy, Physiology, and Pathology, which are here fully and satisfactorily set forth.—*Nashville Journ. of Med. and Surgery*.

We would recommend it to the medical student and practitioner, as containing a summary of all that is known of the important subjects which it treats; of all that is contained in the great works of Simon and Lehmann, and the organic chemists in general. Master this one volume, we would say to the medical student and practitioner—master this book and you know all that is known of the great fundamental principles of medicine, and we have no hesitation in saying that it is an honor to the American medical profession that one of its members should have produced it.—*St. Louis Med. and Surg. Journal*.

**PEREIRA (JONATHAN), M. D., F. R. S., AND L. S.**

**THE ELEMENTS OF MATERIA MEDICA AND THERAPEUTICS.**

Third American edition, enlarged and improved by the author; including Notices of most of the Medicinal Substances in use in the civilized world, and forming an Encyclopædia of Materia Medica. Edited, with Additions, by JOSEPH CARSON, M. D., Professor of Materia Medica and Pharmacy in the University of Pennsylvania. In two very large octavo volumes of 2100 pages, on small type, with about 500 illustrations at stone and wood, strongly bound in leather, with raised bands. \$9 00.

\*\*\* Vol. II. will no longer be sold separate.

**PARKER (LANGSTON),**

Surgeon to the Queen's Hospital, Birmingham.

**THE MODERN TREATMENT OF SYPHILITIC DISEASES, BOTH PRIMARY AND SECONDARY;** comprising the Treatment of Constitutional and Confirmed Syphilis, by a safe and successful method. With numerous Cases, Formulæ, and Clinical Observations. From the Third and entirely rewritten London edition. In one neat octavo volume, extra cloth, of 316 pages. \$1 75.

**ROYLE'S MATERIA MEDICA AND THERAPEUTICS;** including the

Preparations of the Pharmacopœias of London, Edinburgh, Dublin, and of the United States. With many new medicines. Edited by JOSEPH CARSON, M. D. With ninety-eight illustrations. In one large octavo volume, extra cloth, of about 700 pages. \$3 00.

RAMSBOTHAM (FRANCIS H.), M. D.

**THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY**, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the Author. With Additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume, of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful Plates, and numerous Wood-cuts in the text, containing in all nearly 200 large and beautiful figures. \$5 00.

*From Prof. Hodge, of the University of Pa.*

To the American public, it is most valuable, from its intrinsic undoubted excellence, and as being the best authorized exponent of British Midwifery. Its circulation will, I trust, be extensive throughout our country.

It is unnecessary to say anything in regard to the utility of this work. It is already appreciated in our country for the value of the matter, the clearness of its style, and the fulness of its illustrations. To the physician's library it is indispensable, while to the student as a text-book, from which to extract the material for laying the foundation of an education on obstetrical science, it has no superior.—*Ohio Med and Surg. Journal*.

The publishers have secured its success by the

truly elegant style in which they have brought it out, excelling themselves in its production, especially in its plates. It is dedicated to Prof. Meigs, and has the emphatic endorsement of Prof. Hodge, as the best exponent of British Midwifery. We know of no text-book which deserves in all respects to be more highly recommended to students, and we could wish to see it in the hands of every practitioner, for they will find it invaluable for reference.—*Med. Gazette*.

RICORD (P.), M. D.

**A TREATISE ON THE VENEREAL DISEASE.** By JOHN HUNTER, F. R. S. With copious Additions, by PH. RICORD, M. D. Translated and Edited, with Notes, by FREEMAN J. BUMSTEAD, M. D., Lecturer on Venereal at the College of Physicians and Surgeons, New York. Second edition, revised, containing a *résumé* of RICORD'S RECENT LECTURES ON CHANCERE. In one handsome octavo volume, extra cloth, of 550 pages, with eight plates. \$3 25. (*Just Issued.*)

In revising this work, the editor has endeavored to introduce whatever matter of interest the recent investigations of syphilographers have added to our knowledge of the subject. The principal source from which this has been derived is the volume of "Lectures on Chancere," published a few months since by M. Ricord, which affords a large amount of new and instructive material on many controverted points. In the previous edition, M. Ricord's additions amounted to nearly one-third of the whole, and with the matter now introduced, the work may be considered to present his views and experience more thoroughly and completely than any other.

Every one will recognize the attractiveness and value which this work derives from thus presenting the opinions of these two masters side by side. But, it must be admitted, what has made the fortune of the book, is the fact that it contains the "most complete embodiment of the veritable doctrines of the Hôpital du Midi," which has ever been made public. The doctrinal ideas of M. Ricord, ideas which, if not universally adopted, are incontestably dominant, have heretofore only been interpreted by more or less skillful

secretaries, sometimes accredited and sometimes not.

In the notes to Hunter, the master substitutes himself for his interpreters, and gives his original thoughts to the world in a lucid and perfectly intelligible manner. In conclusion we can say that this is incontestably the best treatise on syphilis with which we are acquainted, and, as we do not often employ the phrase, we may be excused for expressing the hope that it may find a place in the library of every physician.—*Virginia Med. and Surg. Journal*.

BY THE SAME AUTHOR.

**RICORD'S LETTERS ON SYPHILIS.** Translated by W. P. LATTIMORE, M. D. In one neat octavo volume, of 270 pages, extra cloth. \$2 00.

ROKITANSKY (CARL), M. D.,

Curator of the Imperial Pathological Museum, and Professor at the University of Vienna, &c.

**A MANUAL OF PATHOLOGICAL ANATOMY.** Four volumes, octavo, bound in two, extra cloth, of about 1200 pages. Translated by W. E. SWAINE, EDWARD SIEVEKING, C. H. MOORE, and G. E. DAY. \$5 50.

The profession is too well acquainted with the reputation of Rokitansky's work to need our assurance that this is one of the most profound, thorough, and valuable books ever issued from the medical press. It is *sui generis*, and has no standard of comparison. It is only necessary to announce that it is issued in a form as cheap as is compatible with its size and preservation, and its sale follows as a matter of course. No library can be called complete without it.—*Buffalo Med. Journal*.

An attempt to give our readers any adequate idea of the vast amount of instruction accumulated in these volumes, would be feeble and hopeless. The effort of the distinguished author to concentrate in a small space his great fund of knowledge, has

so charged his text with valuable truths, that any attempt of a reviewer to epitomize is at once paralyzed, and must end in a failure.—*Western Lancet*.

As this is the highest source of knowledge upon the important subject of which it treats, no real student can afford to be without it. The American publishers have entitled themselves to the thanks of the profession of their country, for this timely and beautiful edition.—*Nashville Journal of Medicine*.

As a book of reference, therefore, this work must prove of inestimable value, and we cannot too highly recommend it to the profession.—*Charleston Med. Journal and Review*.

This book is a necessity to every practitioner.—*Am. Med. Monthly*.

RIGBY (EDWARD), M. D.,

Senior Physician to the General Lying-in Hospital, &c.

**A SYSTEM OF MIDWIFERY.** With Notes and Additional Illustrations. Second American Edition. One volume octavo, extra cloth, 422 pages. \$2 50.

BY THE SAME AUTHOR. (*Lately Published.*)

**ON THE CONSTITUTIONAL TREATMENT OF FEMALE DISEASES.** In one neat royal 12mo. volume, extra cloth, of about 250 pages. \$1 00.

**STILLE (ALFRED), M. D.**

**THERAPEUTICS AND MATERIA MEDICA;** a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. In two large and handsome octavo volumes, of 1789 pages. (*Just Issued.*) \$8 00.

This work is designed especially for the student and practitioner of medicine, and treats the various articles of the *Materia Medica* from the point of view of the bedside, and not of the shop or of the lecture-room. While thus endeavoring to give all practical information likely to be useful with respect to the employment of special remedies in special affections, and the results to be anticipated from their administration, a copious Index of Diseases and their Remedies renders the work eminently fitted for reference by showing at a glance the different means which have been employed, and enabling the practitioner to extend his resources in difficult cases with all that the experience of the profession has suggested.

Rarely, indeed, have we had submitted to us a work on medicine so ponderous in its dimensions as that now before us, and yet so fascinating in its contents. It is, therefore, with a peculiar gratification that we recognize in Dr. Stille the possession of many of those more distinguished qualifications which entitle him to approbation, and which justify him in coming before his medical brethren as an instructor. A comprehensive knowledge, joined to a love of progress—which a discriminating spirit of inquiry has tempered so as to accept nothing new because it is new, and abandon nothing old because it is old, but which estimates either according to its relations to a just logic and experience—manifests itself everywhere, and gives to the guidance of the author all the assurance of safety which the difficulties of his subject can allow. In conclusion, we earnestly advise our readers to ascertain for themselves, by a study of Dr. Stille's volumes, the great value and interest of the stores of knowledge they present. We have pleasure in referring rather to the ample treasury of undoubted truths, the real and assured conquest of medicine, accumulated by Dr. Stille in his pages; and commend the sum of his labors to the attention of our readers, as alike honorable to our science, and creditable to the zeal, the candor, and the judgment of him who has garnered the whole so carefully.—*Edinburgh Med. Journal.*

Our expectations of the value of this work were based on the well-known reputation and character of the author as a man of scholarly attainments, an elegant writer, a candid inquirer after truth, and a philosophical thinker; we knew that the task would be conscientiously performed, and that few, if any, among the distinguished medical teachers in this country are better qualified than he to prepare a systematic treatise on therapeutics in accordance with the present requirements of medical science. Our preliminary examination of the work has satis-

fied us that we were not mistaken in our anticipations.—*New Orleans Medical News*, March, 1860.

The most recent authority is the one last mentioned, Stille. His great work on "*Materia Medica and Therapeutics*," published last year, in two octavo volumes, of some sixteen hundred pages, while it embodies the results of the labor of others up to the time of publication, is enriched with a great amount of original observation and research. We would draw attention, by the way, to the very convenient mode in which the *Index* is arranged in this work. There is first an "*Index of Remedies*;" next an "*Index of Diseases and their Remedies*." Such an arrangement of the Indices, in our opinion, greatly enhances the practical value of books of this kind. In tedious, obstinate cases of disease, where we have to try one remedy after another until our stock is pretty nearly exhausted, and we are almost driven to our wit's end, such an index as the second of the two just mentioned, is precisely what we want.—*London Med. Times and Gazette*, April, 1861.

We think this work will do much to obviate the reluctance to a thorough investigation of this branch of scientific study, for in the wide range of medical literature treasured in the English tongue, we shall hardly find a work written in a style more clear and simple, conveying forcibly the facts taught, and yet free from turgidity and redundancy. There is a fascination in its pages that will insure to it a wide popularity and attentive perusal, and a degree of usefulness not often attained through the influence of a single work. The author has much enhanced the practical utility of his book by passing briefly over the physical, botanical, and commercial history of medicines, and directing attention chiefly to their physiological action, and their application for the amelioration or cure of disease. He ignores hypothesis and theory which are so alluring to many medical writers, and so liable to lead them astray, and confines himself to such facts as have been tried in the crucible of experience.—*Chicago Medical Journal.*

**SMITH (HENRY H.), M. D. AND HORNER (WILLIAM E.), M. D.**  
**AN ANATOMICAL ATLAS,** illustrative of the Structure of the Human Body. In one volume, large imperial octavo, extra cloth, with about six hundred and fifty beautiful figures. \$3 00.

These figures are well selected, and present a complete and accurate representation of that wonderful fabric, the human body. The plan of this Atlas, which renders it so peculiarly convenient for the student, and its superb artistical execution, have been already pointed out. We must congratulate

the student upon the completion of this Atlas, as it is the most convenient work of the kind that has yet appeared; and we must add, the very beautiful manner in which it is "got up" is so creditable to the country as to be flattering to our national pride.—*American Medical Journal.*

**SHARPEY (WILLIAM), M. D., JONES QUAIN, M. D., AND RICHARD QUAIN, F. R. S., &c.**

**HUMAN ANATOMY.** Revised, with Notes and Additions, by JOSEPH LEIDY, M. D., Professor of Anatomy in the University of Pennsylvania. Complete in two large octavo volumes, leather, of about thirteen hundred pages. Beautifully illustrated with over five hundred engravings on wood. \$6 00.

**SIMPSON (J. Y.), M. D.,**

Professor of Midwifery, &c., in the University of Edinburgh, &c.

**CLINICAL LECTURES ON THE DISEASES OF FEMALES.** With numerous illustrations.

This valuable series of practical Lectures is now appearing in the "*MEDICAL NEWS AND LIBRARY*" for 1860, 1861, and 1862, and can thus be had without cost by subscribers to the "*AMERICAN JOURNAL OF THE MEDICAL SCIENCES.*" See p. 2.

**BOLLY ON THE HUMAN BRAIN;** its Structure, Physiology, and Diseases. From the Second and much enlarged London edition. In one octavo volume, extra cloth, of 500 pages, with 120 wood-cuts. \$2 00.

**KEY'S OPERATIVE SURGERY.** In one very

handsome octavo volume, extra cloth, of over 650 pages, with about one hundred wood-cuts. \$3 25.  
**SIMON'S GENERAL PATHOLOGY,** as conducive to the Establishment of Rational Principles for the prevention and Cure of Disease. In one octavo volume, extra cloth, of 212 pages. \$1 25.

SARGENT (F. W.), M. D.

## ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY.

New edition, with an additional chapter on Military Surgery. One handsome royal 12mo. vol., of nearly 400 pages, with 184 wood cuts. Leather, \$1 50. (*Now Ready*)

The value of this work as a handy and convenient manual for surgeons engaged in active duty in the field and hospital, has induced the publishers to render it more complete for those purposes by the addition of a chapter on gun-shot wounds and other matters peculiar to military surgery. In its present form, therefore, with no increase in price, it will be found a very cheap and convenient vade-mecum for consultation and reference in the daily exigencies of military as well as civil practice.

We have read Bourgerie's Minor Surgery with pleasure and profit, but in many respects the volume now before us immeasurably transcends it. We consider that no better book could be placed in the hands of an hospital dresser, or the young surgeon, whose education in this respect has not been perfected. We most cordially commend this volume as one which the medical student should most closely study, to perfect himself in these minor surgical operations in which neatness and dexterity are so much required, and on which a great portion of his reputation as a future surgeon must evidently rest. And to the surgeon in practice it must prove itself a valuable volume, as instructive on many points which he may have forgotten.—*British American Journal*, May, 1862.

The instruction given upon the subject of *Bandaging*, is alone of great value, and while the author modestly proposes to instruct the students of medicine, and the younger physicians, we will say that experienced physicians will obtain many exceedingly valuable suggestions by its perusal. Without attempting to particularize further, we will conclude our brief notice by saying, that it will be found one of the most satisfactory manuals for reference in the field, or hospital yet published; thoroughly adapted to the wants of Military surgeons, and at the same time equally useful for ready and convenient reference by surgeons everywhere.—*Buffalo Med. and Surg. Journal*, June, 1862.

SMITH (W. TYLER), M. D.,

Physician Accoucheur to St. Mary's Hospital, &amp;c.

## ON PARTURITION, AND THE PRINCIPLES AND PRACTICE OF OBSTETRICS. In one royal 12mo. volume, extra cloth, of 400 pages. \$1 25.

BY THE SAME AUTHOR.

## A PRACTICAL TREATISE ON THE PATHOLOGY AND TREATMENT OF LEUCORRHEA. With numerous illustrations. In one very handsome octavo volume, extra cloth, of about 250 pages. \$1 50.

TANNER (T. H.), M. D.,

Physician to the Hospital for Women, &amp;c.

## A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS.

To which is added The Code of Ethics of the American Medical Association. Second American Edition. In one neat volume, small 12mo., extra cloth, 87½ cents.

TAYLOR (ALFRED S.), M. D., F. R. S.,

Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital.

MEDICAL JURISPRUDENCE. Fifth American, from the seventh improved and enlarged London edition. With Notes and References to American Decisions, by EDWARD HARTSHORNE, M. D. In one large 8vo. volume, leather, of over 700 pages. (*Now Ready*.) \$3 25.

This standard work having had the advantage of two revisions at the hands of the author since the appearance of the last American edition, will be found thoroughly revised and brought up completely to the present state of the science. As a work of authority, it must therefore maintain its position, both as a text-book for the student, and a compendious treatise to which the practitioner can at all times refer in cases of doubt or difficulty.

No work upon the subject can be put into the hands of students either of law or medicine which will engage them more closely or profitably; and none could be offered to the busy practitioner of either calling, for the purpose of casual or hasty reference, that would be more likely to afford the aid desired. We therefore recommend it as the best and safest manual for daily use.—*American Journal of Medical Sciences*.

It is not excess of praise to say that the volume before us is the very best treatise extant on Medical Jurisprudence. In saying this, we do not wish to be understood as detracting from the merits of the excellent works of Beck, Ryan, Traill, Guy, and others; but in interest and value we think it must be conceded that Taylor is superior to anything that has preceded it.—*N. W. Medical and Surg. Journal*

It is at once comprehensive and eminently practical, and by universal consent stands at the head of

American and British legal medicine. It should be in the possession of every physician, as the subject is one of great and increasing importance to the public as well as to the profession.—*St. Louis Med. and Surg. Journal*.

This work of Dr. Taylor's is generally acknowledged to be one of the ablest extant on the subject of medical jurisprudence. It is certainly one of the most attractive books that we have met with; supplying so much both to interest and instruct, that we do not hesitate to affirm that after having once commenced its perusal, few could be prevailed upon to desist before completing it. In the last London edition, all the newly observed and accurately recorded facts have been inserted, including much that is recent of Chemical, Microscopical, and Pathological research, besides papers on numerous subjects never before published.—*Charleston Med. Journal and Review*.

BY THE SAME AUTHOR.

## ON POISONS, IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. Second American, from a second and revised London edition. In one large octavo volume, of 755 pages, leather. \$3 50.

Mr. Taylor's position as the leading medical jurist of England, has conferred on him extraordinary advantages in acquiring experience on these subjects, nearly all cases of moment being referred to him for examination, as an expert whose testimony is generally accepted as final. The results of his labors, therefore, as gathered together in this volume, carefully weighed and sifted, and presented in the clear and intelligible style for which he is noted, may be received as an acknowledged authority, and as a guide to be followed with implicit confidence.

**TODD (ROBERT BENTLEY), M. D., F. R. S.,**

Professor of Physiology in King's College, London; and

**WILLIAM BOWMAN, F. R. S.,**

Demonstrator of Anatomy in King's College, London.

**THE PHYSIOLOGICAL ANATOMY AND PHYSIOLOGY OF MAN.** With about three hundred large and beautiful illustrations on wood. Complete in one large octavo volume, of 950 pages, leather. Price \$4 50.

Gentlemen who have received portions of this work, as published in the "MEDICAL NEWS AND LIBRARY," can now complete their copies, if immediate application be made. It will be furnished as follows, free by mail, in paper covers, with cloth backs.

PARTS I., II., III. (pp. 25 to 552), \$2 50.

PART IV. (pp. 553 to end, with Title, Preface, Contents, &c.), \$2 00.

Or, PART IV., SECTION II. (pp. 725 to end, with Title, Preface, Contents, &c.), \$1 25.

A magnificent contribution to British medicine, and the American physician who shall fail to peruse it, will have failed to read one of the most instructive books of the nineteenth century.—*N. O. Med and Surg. Journal.*

It is more concise than Carpenter's Principles, and more modern than the accessible edition of Müller's Elements; its details are brief, but sufficient; its descriptions vivid; its illustrations exact and copious; and its language terse and perspicuous.—*Charleston Med. Journal.*

We know of no work on the subject of physiology

so well adapted to the wants of the medical student. Its completion has been thus long delayed, that the authors might secure accuracy by personal observation.—*St. Louis Med. and Surg. Journal.*

Our notice, though it conveys but a very feeble and imperfect idea of the magnitude and importance of the work now under consideration, already transcends our limits; and, with the indulgence of our readers, and the hope that they will peruse the book for themselves, as we feel we can with confidence recommend it, we leave it in their hands.—*The Northwestern Med. and Surg. Journal.*

**TODD (R. B.) M. D., F. R. S., &c.**

**CLINICAL LECTURES ON CERTAIN DISEASES OF THE URINARY ORGANS AND ON DROPSIES.** In one octavo volume, 284 pages. \$1 50.

BY THE SAME AUTHOR. (*Now Ready.*)

**CLINICAL LECTURES ON CERTAIN ACUTE DISEASES.** In one neat octavo volume, of 320 pages, extra cloth. \$1 75.

**TOYNBEE (JOSEPH), F. R. S.,**

Aural Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital.

**A PRACTICAL TREATISE ON DISEASES OF THE EAR;** their Diagnosis, Pathology, and Treatment. Illustrated with one hundred engravings on wood. In one very handsome octavo volume, extra cloth, \$3 00. (*Just Issued.*)

The work, as was stated at the outset of our notice, is a model of its kind, and every page and paragraph of it are worthy of the most thorough study. Considered all in all—as an original work, well written, philosophically elaborated, and happily illustrated with cases and drawings—it is by far the ablest monograph that has ever appeared on the anatomy and diseases of the ear, and one of the most valuable contributions to the art and science of surgery in the nineteenth century.—*N. Amer. Medical-Chirurg. Review*, Sept. 1860.

To recommend such a work, even after the mere hint we have given of its original excellence and value, would be a work of supererogation. We are speaking within the limits of modest acknowledgment,

and with a sincere and unbiassed judgment, when we affirm that as a treatise on Aural Surgery, it is without a rival in our language or any other.—*Charleston Med. Journ and Review*, Sept. 1860.

The work of Mr. Toynbee is undoubtedly, upon the whole, the most valuable production of the kind in any language. The author has long been known by his numerous monographs upon subjects connected with diseases of the ear, and is now regarded as the highest authority on most points in his department of science. Mr. Toynbee's work, as we have already said, is undoubtedly the most reliable guide for the study of the diseases of the ear in any language, and should be in the library of every physician.—*Chicago Med. Journal*, July, 1860.

**WILLIAMS (C. J. B.), M. D., F. R. S.,**

Professor of Clinical Medicine in University College, London, &c.

**PRINCIPLES OF MEDICINE.** An Elementary View of the Causes, Nature, Treatment, Diagnosis, and Prognosis of Disease; with brief remarks on Hygienics, or the preservation of health. A new American, from the third and revised London edition. In one octavo volume, leather, of about 500 pages. \$2 50. (*Just Issued.*)

We find that the deeply-interesting matter and style of this book have so far fascinated us, that we have unconsciously hung upon its pages, not too long, indeed, for our own profit, but longer than reviewers can be permitted to indulge. We leave the further analysis to the student and practitioner. Our judgment of the work has already been sufficiently

expressed. It is a judgment of almost unqualified praise.—*London Lancet.*

A text-book to which no other in our language is comparable.—*Charleston Medical Journal.*

No work has ever achieved or maintained a more deserved reputation.—*Va. Med. and Surg. Journal.*

## WHAT TO OBSERVE

**AT THE BEDSIDE AND AFTER DEATH, IN MEDICAL CASES.**

Published under the authority of the London Society for Medical Observation. A new American, from the second and revised London edition. In one very handsome volume, royal 12mo., extra cloth. \$1 00.

To the observer who prefers accuracy to blunders and precision to carelessness, this little book is invaluable.—*N. H. Journal of Medicine.*

One of the finest aids to a young practitioner we have ever seen.—*Peninsular Journal of Medicine.*

New and much enlarged edition—(Just Issued.)

WATSON (THOMAS), M. D., &c.,  
Late Physician to the Middlesex Hospital, &c.

## LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC.

Delivered at King's College, London. A new American, from the last revised and enlarged English edition, with Additions, by D. FRANCIS CONDIE, M. D., author of "A Practical Treatise on the Diseases of Children," &c. With one hundred and eighty-five illustrations on wood. In one very large and handsome volume, imperial octavo, of over 1200 closely printed pages in small type; the whole strongly bound in leather, with raised bands. Price \$4 25.

That the high reputation of this work might be fully maintained, the author has subjected it to a thorough revision; every portion has been examined with the aid of the most recent researches in pathology, and the results of modern investigations in both theoretical and practical subjects have been carefully weighed and embodied throughout its pages. The watchful scrutiny of the editor has likewise introduced whatever possesses immediate importance to the American physician in relation to diseases incident to our climate which are little known in England, as well as those points in which experience here has led to different modes of practice; and he has also added largely to the series of illustrations, believing that in this manner valuable assistance may be conveyed to the student in elucidating the text. The work will, therefore, be found thoroughly on a level with the most advanced state of medical science on both sides of the Atlantic.

The additions which the work has received are shown by the fact that notwithstanding an enlargement in the size of the page, more than two hundred additional pages have been necessary to accommodate the two large volumes of the London edition (which sells at ten dollars), within the compass of a single volume, and in its present form it contains the matter of at least three ordinary octavos. Believing it to be a work which should lie on the table of every physician, and be in the hands of every student, the publishers have put it at a price within the reach of all, making it one of the cheapest books as yet presented to the American profession, while at the same time the beauty of its mechanical execution renders it an exceedingly attractive volume.

The fourth edition now appears, so carefully revised, as to add considerably to the value of a book already acknowledged, wherever the English language is read, to be beyond all comparison the best systematic work on the Principles and Practice of Physic in the whole range of medical literature. Every lecture contains proof of the extreme anxiety of the author to keep pace with the advancing knowledge of the day, and to bring the results of the labors, not only of physicians, but of chemists and histologists, before his readers, wherever they can be turned to useful account. One scarcely knows whether to admire most the pure, simple, forcible English—the vast amount of useful practical information condensed into the Lectures—or the manly, kind-hearted, unassuming character of the lecturer shining through his work.—*Lond. Med. Times.*

Thus these admirable volumes come before the profession in their fourth edition, abounding in those distinguished attributes of moderation, judgment, erudite cultivation, clearness, and eloquence, with which they were from the first invested, but yet richer than before in the results of more prolonged observation, and in the able appreciation of the latest advances in pathology and medicine by one of the most profound medical thinkers of the day.—*London Lancet.*

The lecturer's skill, his wisdom, his learning, are equalled by the ease of his graceful diction, his eloquence, and the far higher qualities of candor, of courtesy, of modesty, and of generous appreciation of merit in others.—*N. A. Med.-Chir. Review.*

Watson's unrivalled, perhaps unapproachable work on Practice—the copious additions made to which (the fourth edition) have given it all the novelty and much of the interest of a new book.—*Charleston Med. Journal.*

Lecturers, practitioners, and students of medicine will equally hail the reappearance of the work of Dr. Watson in the form of a new—a fourth—edition. We merely do justice to our own feelings, and, we are sure, of the whole profession, if we thank him for having, in the trouble and turmoil of a large practice, made leisure to supply the hiatus caused by the exhaustion of the publisher's stock of the third edition, which has been severely felt for the last three years. For Dr. Watson has not merely caused the lectures to be reprinted, but scattered through the whole work we find additions or alterations which prove that the author has in every way sought to bring up his teaching to the level of the most recent acquisitions in science.—*Brit. and For. Medico-Chir. Review.*

WALSHE (W. H.), M. D.,

Professor of the Principles and Practice of Medicine in University College, London, &c.

## A PRACTICAL TREATISE ON DISEASES OF THE LUNGS; including the Principles of Physical Diagnosis. A new American, from the third revised and much enlarged London edition. In one vol. octavo, of 468 pages. (Just Issued, June, 1860.) \$2 25.

The present edition has been carefully revised and much enlarged, and may be said in the main to be rewritten. Descriptions of several diseases, previously omitted, are now introduced; the causes and mode of production of the more important affections, so far as they possess direct practical significance, are succinctly inquired into; an effort has been made to bring the description of anatomical characters to the level of the wants of the practical physician; and the diagnosis and prognosis of each complaint are more completely considered. The sections on TREATMENT and the Appendix (concerning the influence of climate on pulmonary disorders), have, especially, been largely extended.—*Author's Preface.*

BY THE SAME AUTHOR.

## A PRACTICAL TREATISE ON THE DISEASES OF THE HEART AND GREAT VESSELS, including the Principles of Physical Diagnosis. Third American, from the third revised and much enlarged London edition. In one handsome octavo volume of 420 pages, extra cloth. \$2 25. (Just Ready.)

From the Author's Preface.

The present edition has been carefully revised; much new matter has been added, and the entire work in a measure remodelled. Numerous facts and discussions, more or less completely novel, will be found in the description of the principles of physical diagnosis; but the chief additions have been made in the practical portions of the book. Several affections, of which little or no account had been given in the previous editions, are now treated of in detail. Functional disorders of the heart, the frequency of which is almost rivalled by the misery they inflict, have been closely reconsidered; more especially an attempt has been made to render their essential nature clearer, and consequently their treatment more successful, by an analysis of their dynamic elements.

New and much enlarged edition—(Just Issued.)

WILSON (ERASMUS), F. R. S.

**A SYSTEM OF HUMAN ANATOMY**, General and Special. A new and revised American, from the last and enlarged English Edition. Edited by W. H. GOBRECHT, M. D., Professor of Anatomy in the Pennsylvania Medical College, &c. Illustrated with three hundred and ninety-seven engravings on wood. In one large and exquisitely printed octavo volume, of over 600 large pages; leather. \$3 25.

The publishers trust that the well earned reputation so long enjoyed by this work will be more than maintained by the present edition. Besides a very thorough revision by the author, it has been most carefully examined by the editor, and the efforts of both have been directed to introducing everything which increased experience in its use has suggested as desirable to render it a complete text-book for those seeking to obtain or to renew an acquaintance with Human Anatomy. The amount of additions which it has thus received may be estimated from the fact that the present edition contains over one-fourth more matter than the last, rendering a smaller type and an enlarged page requisite to keep the volume within a convenient size. The editor has exercised the utmost caution to obtain entire accuracy in the text, and has largely increased the number of illustrations, of which there are about one hundred and fifty more in this edition than in the last, thus bringing distinctly before the eye of the student everything of interest or importance.

It may be recommended to the student as no less distinguished by its accuracy and clearness of description than by its typographical elegance. The wood-cuts are exquisite.—*Brit. and For. Medical Review*.

An elegant edition of one of the most useful and accurate systems of anatomical science which has been issued from the press. The illustrations are really beautiful. In its style the work is extremely concise and intelligible. No one can possibly take up this volume without being struck with the great

beauty of its mechanical execution, and the clearness of the descriptions which it contains is equally evident. Let students, by all means examine the claims of this work on their notice, before they purchase a text-book of the vitally important science which this volume so fully and easily unfolds.—*Lancet*.

We regard it as the best system now extant for students.—*Western Lancet*.

It therefore receives our highest commendation.—*Southern Med. and Surg. Journal*.

BY THE SAME AUTHOR. (Just Issued.)

**ON DISEASES OF THE SKIN.** Fourth and enlarged American, from the last and improved London edition. In one large octavo volume, of 650 pages, extra cloth, \$2 75.

The writings of Wilson, upon diseases of the skin, are by far the most scientific and practical that have ever been presented to the medical world on this subject. The present edition is a great improvement on all its predecessors. To dwell upon all the great merits and high claims of the work before us, *seriatim*, would indeed be an agreeable service; it would be a mental homage which we could freely offer, but we should thus occupy an undue amount of space in this *Journal*. We will, however, look

at some of the more salient points with which it abounds, and which make it incomparably superior in excellence to all other treatises on the subject of dermatology. No mere speculative views are allowed a place in this volume, which, without a doubt, will, for a very long period, be acknowledged as the chief standard work on dermatology. The principles of an enlightened and rational therapeia are introduced on every appropriate occasion.—*Am. Jour. Med. Science*, Oct. 1857.

ALSO, NOW READY,

**A SERIES OF PLATES ILLUSTRATING WILSON ON DISEASES OF THE SKIN**; consisting of nineteen beautifully executed plates, of which twelve are exquisitely colored, presenting the Normal Anatomy and Pathology of the Skin, and containing accurate representations of about one hundred varieties of disease, most of them the size of nature. Price in cloth \$4 25.

In beauty of drawing and accuracy and finish of coloring these plates will be found equal to anything of the kind as yet issued in this country.

The plates by which this edition is accompanied leave nothing to be desired, so far as excellence of delineation and perfect accuracy of illustration are concerned.—*Medico-Chirurgical Review*.

Of these plates it is impossible to speak too highly. The representations of the various forms of cutaneous disease are singularly accurate, and the coloring exceeds almost anything we have met with in point of delicacy and finish.—*British and Foreign Medical Review*.

We have already expressed our high appreciation of Mr. Wilson's treatise on Diseases of the Skin. The plates are comprised in a separate volume, which we counsel all those who possess the text to purchase. It is a beautiful specimen of color printing, and the representations of the various forms of skin disease are as faithful as is possible in plates of the size.—*Boston Med. and Surg. Journal*, April 8, 1853.

BY THE SAME AUTHOR.

**ON CONSTITUTIONAL AND HEREDITARY SYPHILIS, AND ON SYPHILITIC ERUPTIONS.** In one small octavo volume, extra cloth, beautifully printed, with four exquisite colored plates, presenting more than thirty varieties of syphilitic eruptions. \$2 25.

BY THE SAME AUTHOR.

**HEALTHY SKIN; A Popular Treatise on the Skin and Hair, their Preservation and Management.** Second American, from the fourth London edition. One neat volume, royal 12mo., extra cloth, of about 300 pages, with numerous illustrations. \$1 00; paper cover, 75 cents.

BY THE SAME AUTHOR.

**THE DISSECTOR'S MANUAL; or, Practical and Surgical Anatomy.** Third American, from the last revised and enlarged English edition. Modified and rearranged, by WILLIAM HUNT, M. D., Demonstrator of Anatomy in the University of Pennsylvania. In one large and handsome royal 12mo. volume, leather, of 592 pages, with 154 illustrations. \$2 00.

WINSLOW (FORBES), M. D., D. C. L., &amp;c.

## ON OBSCURE DISEASES OF THE BRAIN AND DISORDERS OF THE

MIND; their incipient Symptoms, Pathology, Diagnosis, Treatment, and Prophylaxis. In one handsome octavo volume, of nearly 600 pages. (Just Issued.) \$3 00.

We close this brief and necessarily very imperfect notice of Dr. Winslow's great and classical work, by expressing our conviction that it is long since so important and beautifully written a volume has issued from the British medical press.—*Dublin Med. Press*, July 25, 1860.

We honestly believe this to be the best book of the season.—*Banking's Abstract*, July, 1860.

It carried us back to our old days of novel reading, it kept us from our dinner, from our business, and from our slumbers; in short, we laid it down only when we had got to the end of the last paragraph, and even then turned back to the perpetual of several passages which we had marked as requiring further study. We have failed entirely in the above notice to give an adequate acknowledgment of the profit and pleasure with which we have perused the above work. We can only say to our readers, study it

yourselves; and we extend the invitation to unprofessional as well as professional men, believing that it contains matter deeply interesting not to physicians alone, but to all who appreciate the truth that: "The proper study of mankind is man."—*Nashville Medical Record*, July, 1860.

The latter portion of Dr. Winslow's work is exclusively devoted to the consideration of Cerebral Pathology. It completely exhausts the subject, in the same manner as the previous seventeen chapters relating to morbid psychical phenomena left nothing unnoticed in reference to the mental symptoms premonitory of cerebral disease. It is impossible to overrate the benefits likely to result from a general perusal of Dr. Winslow's valuable and deeply interesting work.—*London Lancet*, June 23, 1860.

It contains an immense mass of information.—*Brit. and For. Med.-Chir. Review*, Oct. 1860.

WEST (CHARLES), M. D.,

Accoucheur to and Lecturer on Midwifery at St. Bartholomew's Hospital, Physician to the Hospital for Sick Children, &c.

LECTURES ON THE DISEASES OF WOMEN. Second American, from the second London edition. In one handsome octavo volume, extra cloth, of about 500 pages; price \$2 50. (Now Ready, July, 1861.)

\* \* \* Gentlemen who received the first portion, as issued in the "Medical News and Library," can now complete their copies by procuring Part II, being page 309 to end, with Index, Title matter, &c., 8vo., cloth, price \$1.

We must now conclude this hastily written sketch with the confident assurance to our readers that the work will well repay perusal. The conscientious, painstaking, practical physician is apparent on every page.—*N. Y. Journal of Medicine*, March, 1858.

We know of no treatise of the kind so complete and yet so compact.—*Chicago Med. Jour.* Jan. 1858.

A fairer, more honest, more earnest, and more reliable investigator of the many diseases of women and children is not to be found in any country.—*Southern Med. and Surg. Journal*, January 1858.

We gladly recommend his Lectures as in the highest degree instructive to all who are interested in obstetric practice.—*London Lancet*.

We have to say of it, briefly and decidedly, that it is the best work on the subject in any language; and that it stamps Dr. West as the facile princeps of British obstetric authors.—*Edinb. Med. Journ.*

As a writer, Dr. West stands, in our opinion, second only to Watson, the "Macaulay of Medicine;" he possesses that happy faculty of clothing instruc-

tion in easy garments; combining pleasure with profit, he leads his pupils, in spite of the ancient proverb, along a royal road to learning. His work is one which will not satisfy the extreme on either side, but it is one that will please the great majority who are seeking truth, and one that will convince the student that he has committed himself to a candid, safe, and valuable guide.—*N. A. Med.-Chirurg. Review*, July, 1858.

Happy in his simplicity of manner, and moderate in his expression of opinion, the author is a sound reasoner and a good practitioner, and his book is worthy of the handsome garb in which it has appeared.—*Virginia Med. Journal*.

We must take leave of Dr. West's very useful work, with our commendation of the clearness of its style, and the industry and sobriety of judgment of which it gives evidence.—*London Med. Times*.

Sound judgment and good sense pervade every chapter of the book. From its perusal we have derived unmixed satisfaction.—*Dublin Quart. Journ.*

BY THE SAME AUTHOR. (Just Issued.)

## LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Third American, from the fourth enlarged and improved London edition. In one handsome octavo volume, extra cloth, of about six hundred and fifty pages. \$2 75.

The three former editions of the work now before us have placed the author in the foremost rank of those physicians who have devoted special attention to the diseases of early life. We attempt no analysis of this edition, but may refer the reader to some of the chapters to which the largest additions have been made—those on Diphtheria, Disorders of the Mind, and Idiocy, for instance—as a proof that the work is really a new edition; not a mere reprint. In its present shape it will be found of the greatest possible service in the every-day practice of nine-tenths of the profession.—*Med. Times and Gazette*, London, Dec. 10, 1859.

All things considered, this book of Dr. West is by far the best treatise in our language upon such modifications of morbid action and disease as are witnessed when we have to deal with infancy and childhood. It is true that it confines itself to such disorders as come within the province of the physician, and even with respect to these it is unequal as regards minuteness of consideration, and some

diseases it omits to notice altogether. But those who know anything of the present condition of pediatrics will readily admit that it would be next to impossible to effect more, or effect it better, than the accoucheur of St. Bartholomew's has done in a single volume. The lecture (XVI.) upon Disorders of the Mind in children is an admirable specimen of the value of the later information conveyed in the Lectures of Dr. Charles West.—*London Lancet*, Oct. 22, 1859.

Since the appearance of the first edition, about eleven years ago, the experience of the author has doubled; so that, whereas the lectures at first were founded on six hundred observations, and one hundred and eighty dissections made among nearly fourteen thousand children, they now embody the results of nine hundred observations, and two hundred and eighty-eight post-mortem examinations made among nearly thirty thousand children, who, during the past twenty years, have been under his care.—*British Med. Journal*, Oct. 1, 1859.
